Applied Databases

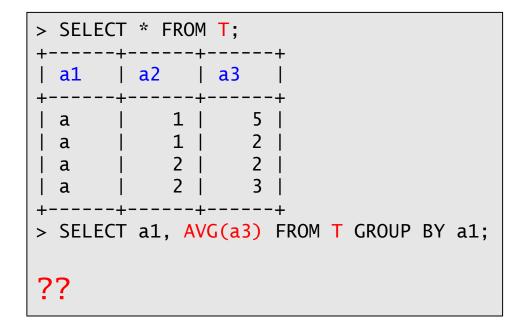

Lecture 8 SQL and Beyond

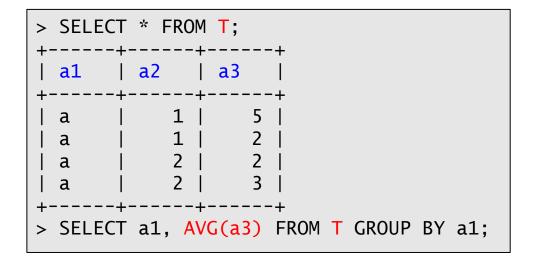

Sebastian Maneth

University of Edinburgh - February 4th, 2016

Outline

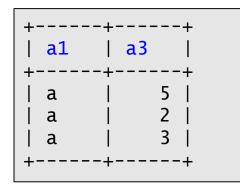

- 1. More on Aggregates
- 2. Joins
- 3. Limits of SQL

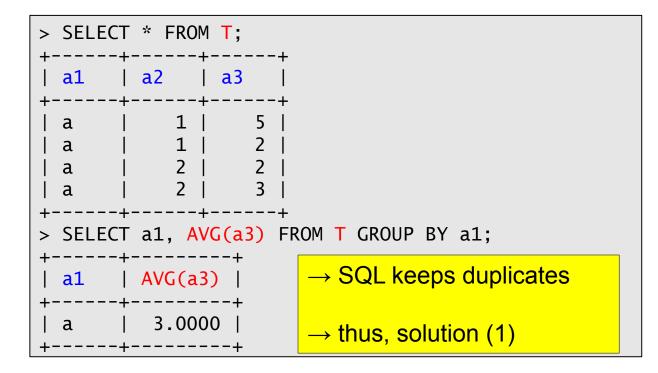

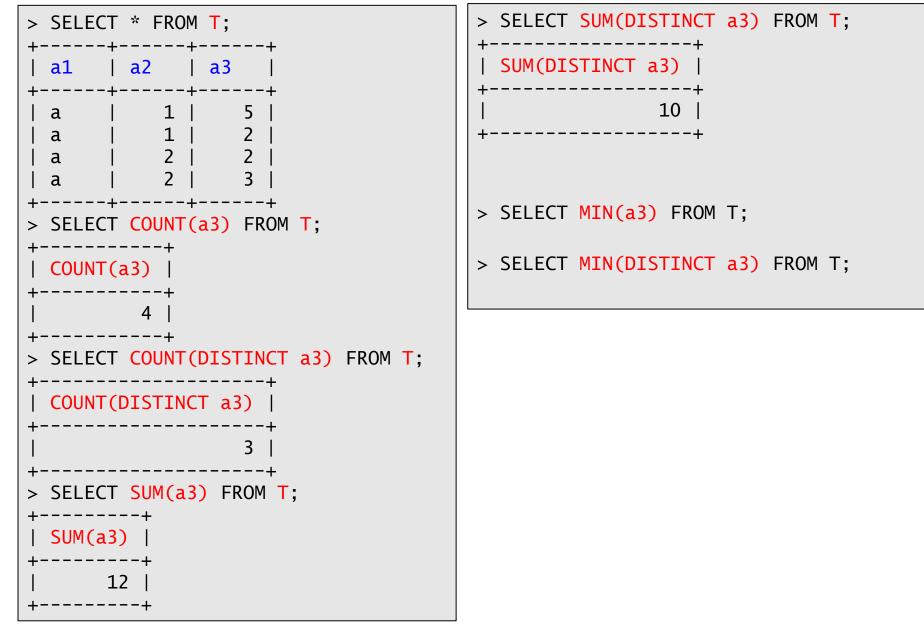

(1) take all a3-values and compute average: (5+2+2+3)/4 = 3

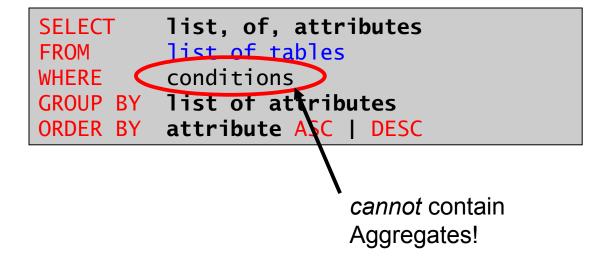

(2) only (a1,a3) are relevant, so, we project onto (a1,a3) to get

average now:
$$(5 + 2 + 3) / 3 = 10 / 3$$

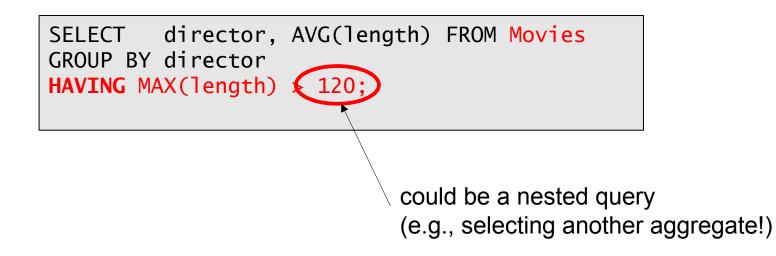

SELECT	list, of, attributes
FROM	list of tables
WHERE	conditions
GROUP BY	list of attributes
ORDER BY	attribute ASC DESC
HAVING	AGGREGATE(attribute) operator value

 $\rightarrow\,$ find directors and average length of their movies, provided they made at least one movie that is longer than 2 hours

SELECT director, AVG(length) FROM Movies
GROUP BY director
HAVING MAX(length) > 120;

SELECT	list, of, attributes
FROM	list of tables
WHERE	conditions
GROUP BY	list of attributes
ORDER BY	attribute ASC DESC
HAVING	AGGREGATE(attribute) operator value

 $\rightarrow\,$ find directors and average length of their movies, provided they made at least one movie that is longer than 2 hours

• Find movies that are shorter than some currently playing movie:

```
SELECT M.Title

FROM Movies M

WHERE M.length < (SELECT MAX M1.length)

FROM Movies M1, Schedule S

WHERE M1.title=S.title)
```

or

SELECT M.Title FROM Movies M WHERE M.length < ANY SELECT M1.length FROM Movies M1, Schedule S WHERE M1.title=S.title)

- <value> <condition> ANY (<query>)
 is true if for some <value1> in the result of <query>,
 <value> <condition> <value1> is true.
- For example,
 - $5 < ANY(\emptyset)$ is false; $5 < ANY(\{1, 2, 3, 4\}$ is false; $5 < ANY(\{1, 2, 3, 4, 5, 6\}$ is true.

• <value> <condition> ALL (<query>)
is true if either:

o <query> evaluates to the empty set, or o for every <value1> in the result of <query>, <value> <condition> <value1> is true.

- For example,
 - $5 > ALL(\emptyset)$ is true; $5 > ALL(\{1, 2, 3\}$ is true; $5 > ALL(\{1, 2, 3, 4, 5, 6\}$ is false.

What is special about databases?

→ transaction processing (data is safe, multi-user support) → SQL

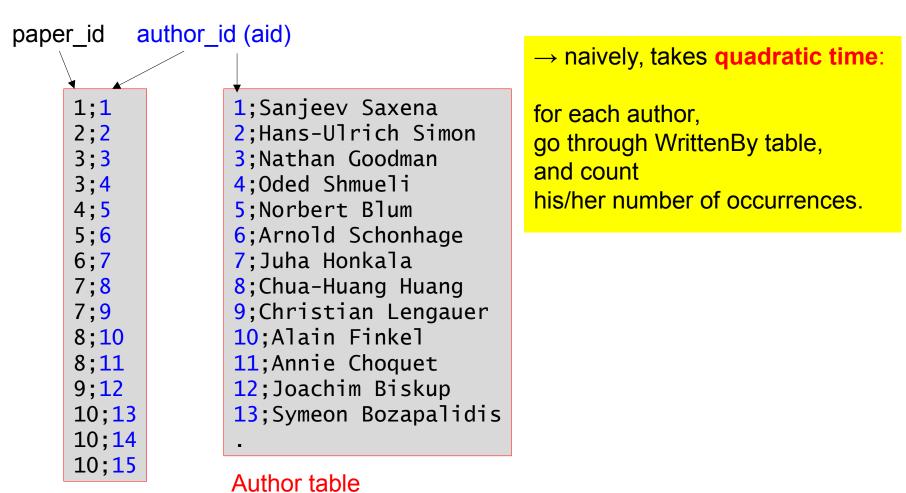

What is special about SQL?

- \rightarrow mature standard
- \rightarrow widely adopted / used in industry
- $\rightarrow\,$ expressiveness and efficiency
 - (*) all queries terminate
 - (*) data complexity is polynomial time

What is the most important (and expensive) SQL operation?

 \rightarrow the JOIN.

 \rightarrow for each author, find the number of papers he/she wrote

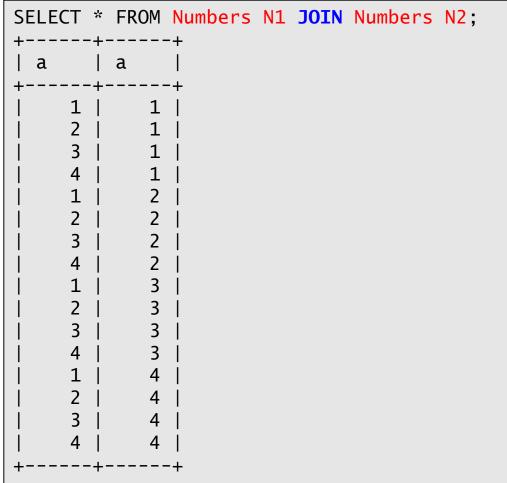

WrittenBy table

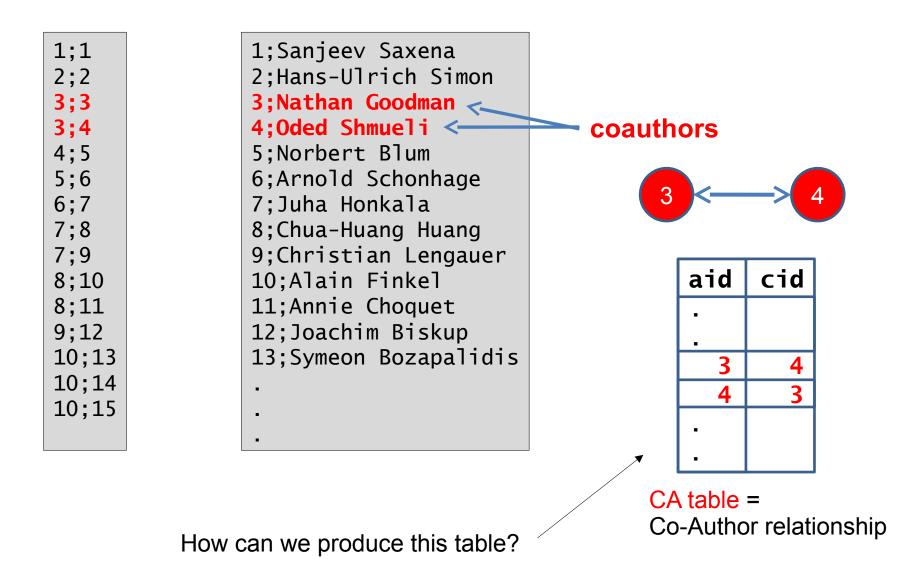

15

- \rightarrow the simplest join is just the Cartesian product.
- \rightarrow its size is quadratic!

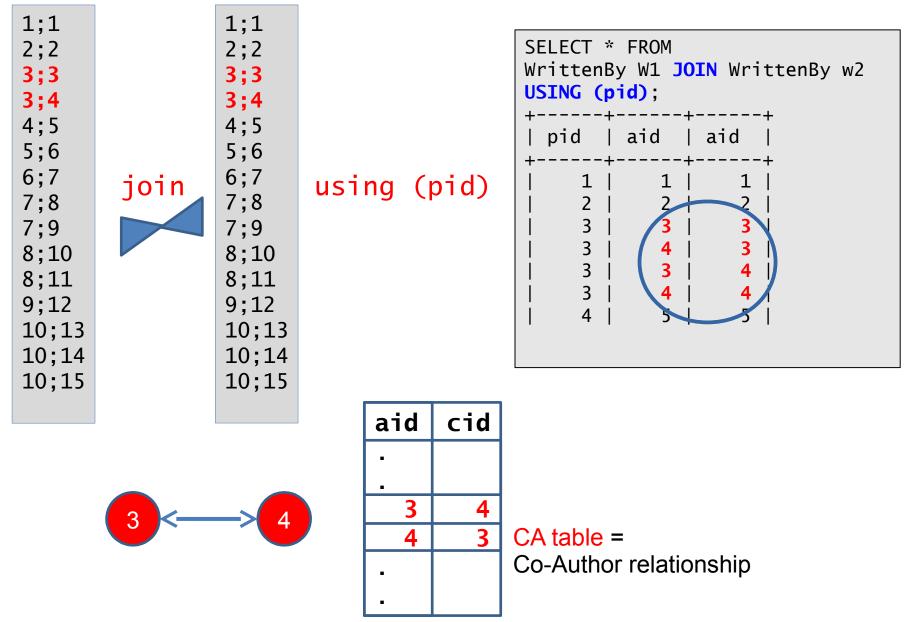

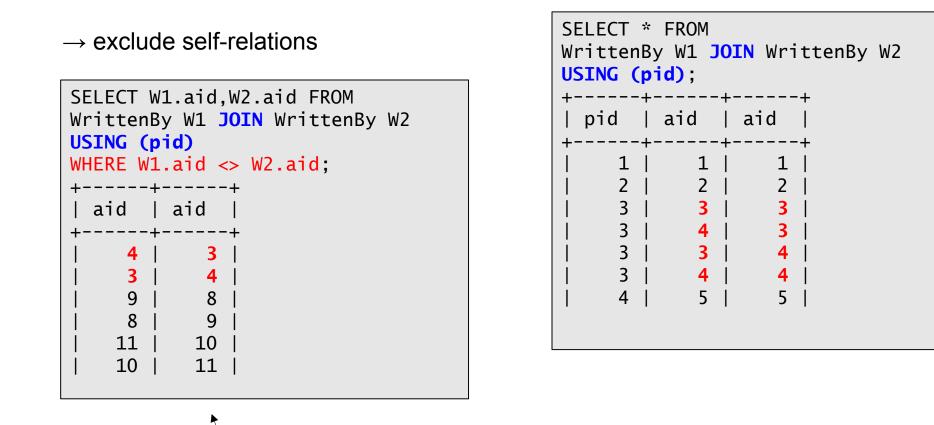

Co-Author Graph

Co-Author Graph

Co-Author Graph

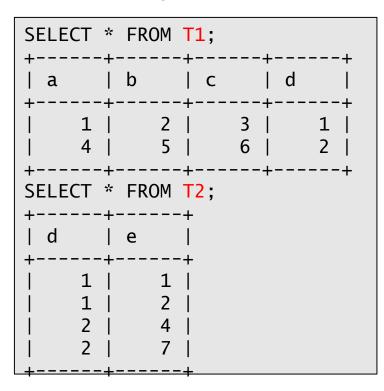

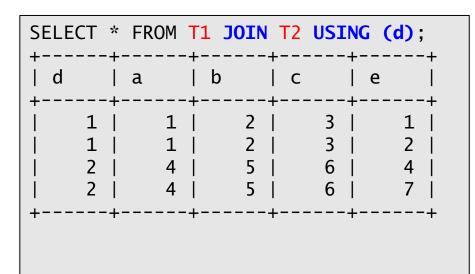

Correctly produces the Co-Author Graph!

Table1 JOIN Table2 USING (c1, c2, ..., cN)

→ joins all tuples of Table1 and Table2 which agree on their c1,..,cN values Careful! → order depends on implementation. (mysql)

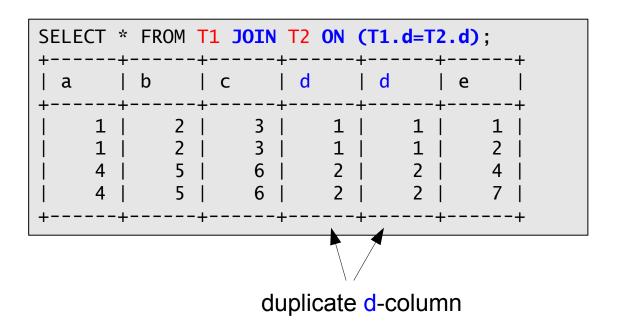

→ result table has columns c1,..,cN, followed by the columns of Table1 that are not in { c1,..,cN } followed by the columns of Table2 that are not in { c1,..,cN }

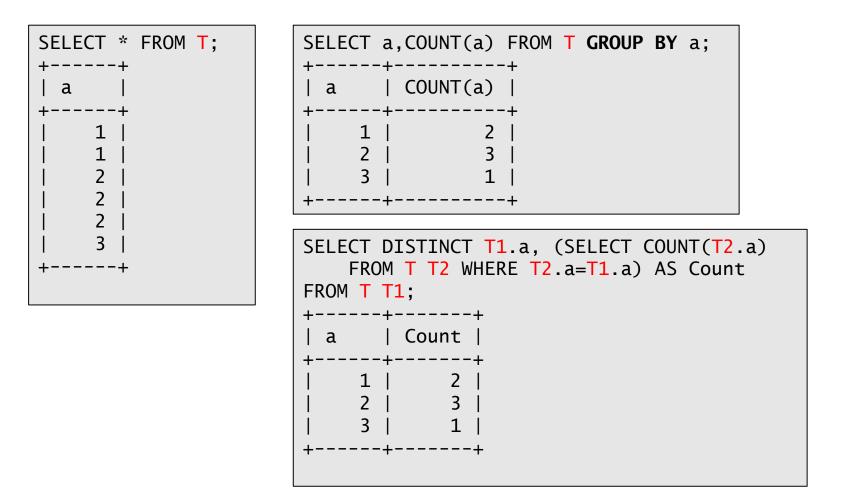

T1 JOIN T2 ON (T1.c1=T2.d1 AND T1.c2<=T2.d2 OR NOT(...))

- \rightarrow joins all tuples of Table1 and Table2 which satisfy join condition
- → result table has all columns of Table1 followed by all columns of Table2

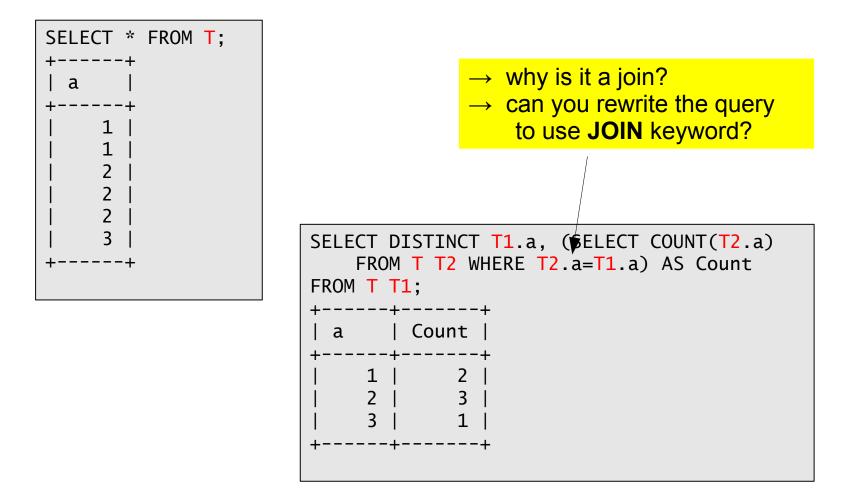

- \rightarrow joins are quite powerful!
- \rightarrow E.g. simulate "**GROUP BY**" through a join:

 \rightarrow joins are quite powerful!

 \rightarrow E.g. simulate "GROUP BY" through a join:

 \rightarrow joins are quite powerful!

 \rightarrow E.g. simulate "**GROUP BY**" through a join:

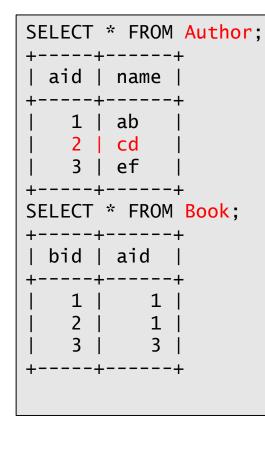

→ similarly, you can avoid HAVING by the use of a JOIN

 \rightarrow do you see how ?

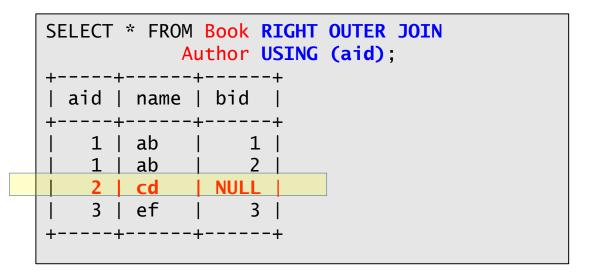

Outer Joins

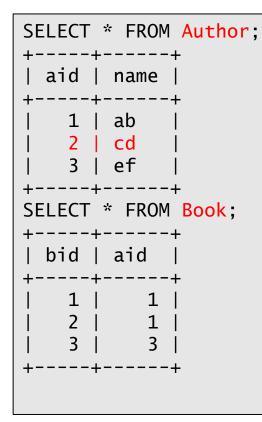

Outer Joins

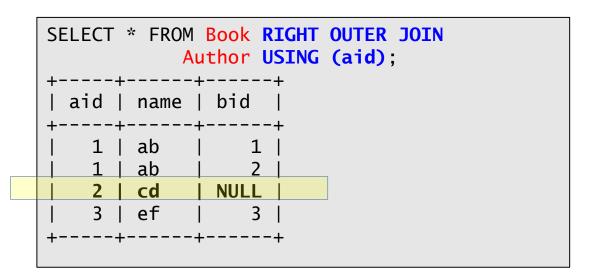

SELECT *				Author	USING	(aid);	
aid	bid	•	•				
++ 1 1 3 ++	1 2	ab	•				

Outer Joins

SELECT aid,coun FROM Book RIGHT Author USING GROUP BY aid;	
aid n_books	-+
++	-+
2 0 3 1	
++	-+

Table1 RIGHT OUTER JOIN Table2 USING / ON ...

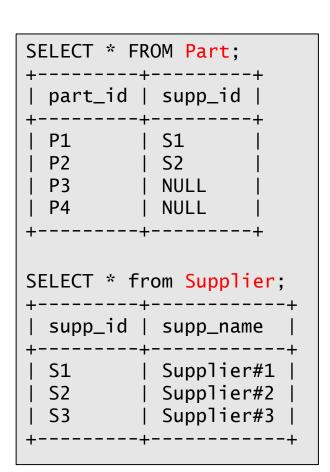

- \rightarrow joins all tuples of Table1 and Table1 satisfying join condition, plus all remaining tuples from Table2 (the RIGHT)
- \rightarrow result tuples of the second type above have **NULL-values** in the columns coming from Table1.

Table1 RIGHT OUTER JOIN Table2 USING / ON ...

- \rightarrow joins all tuples of Table1 and Table1 satisfying join condition, plus all remaining tuples from Table2 (the RIGHT)
- \rightarrow result tuples of the second type above have **NULL-values** in the columns coming from Table1.

Table1 LEFT OUTER JOIN Table2 USING / ON ...

- → joins all tuples of Table1 and Table2 satisfying join condition, plus all remaining tuples from Table1 (the LEFT)
- \rightarrow result tuples of the second type above have **NULL-values** in the columns coming from Table2.

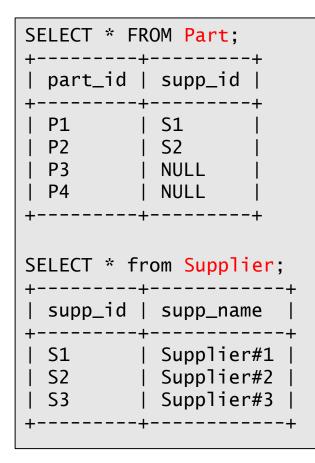

Outer J	oins	common attributes
SELECT * FR	OM Part NA	TURAL JOIN Supplier;
supp_id	part_id	supp_name
S1 S2 ++	P1 P2	Supplier#1 Supplier#2 +

Outor Joine

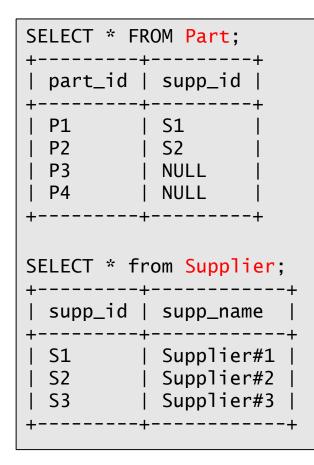

Join on all

Left Outer Join

SELECT part_id,supp_name FROM Part NATURAL LEFT JOIN Supplier;		
• •	supp_name	
· · ·	Supplier#1 Supplier#2 NULL NULL	

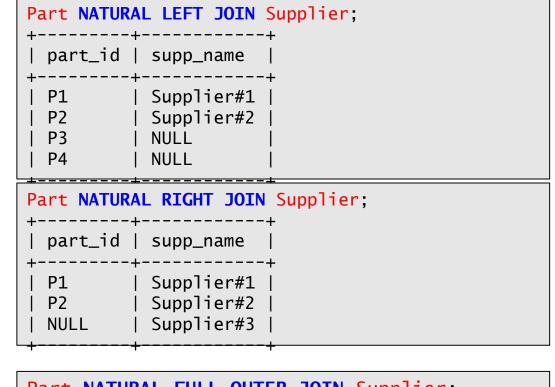

Right Outer Join

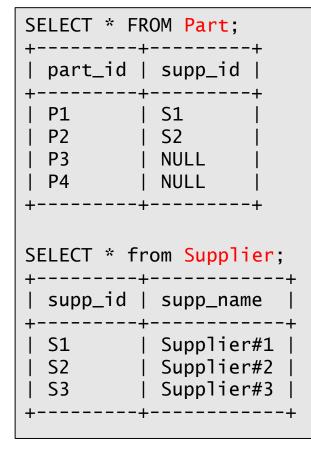

SELECT part_id,supp_name FROM Part NATURAL LEFT JOIN Supplier;		
part_id	•	
•	Supplier#1 Supplier#2 NULL NULL	

SELECT part_id,supp_name FROM Part NATURAL RIGHT JOIN Supplier;		
part_id	supp_name ++	
-	Supplier#1 Supplier#2 Supplier#3 ++	

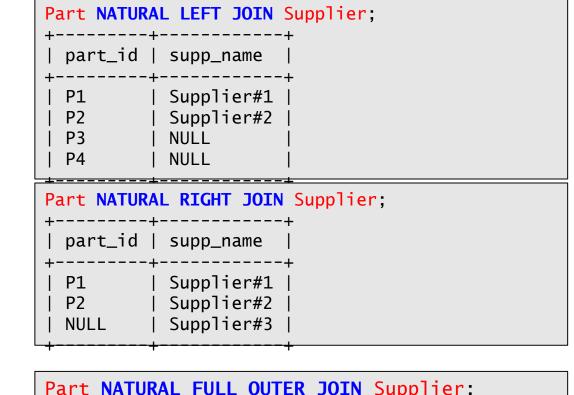

Full Outer Join

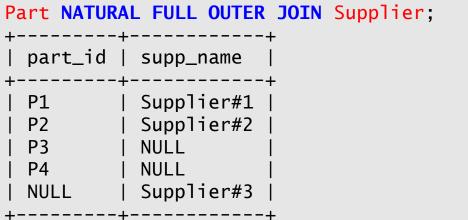

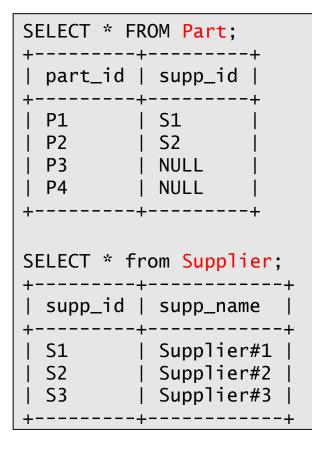

Part NATURA	L FULL OUTER JOIN Supplier;
part_id	supp_name
++ P1 P2 P3 P4 NULL	Supplier#1 Supplier#2 NULL NULL Supplier#3

Full Outer Join

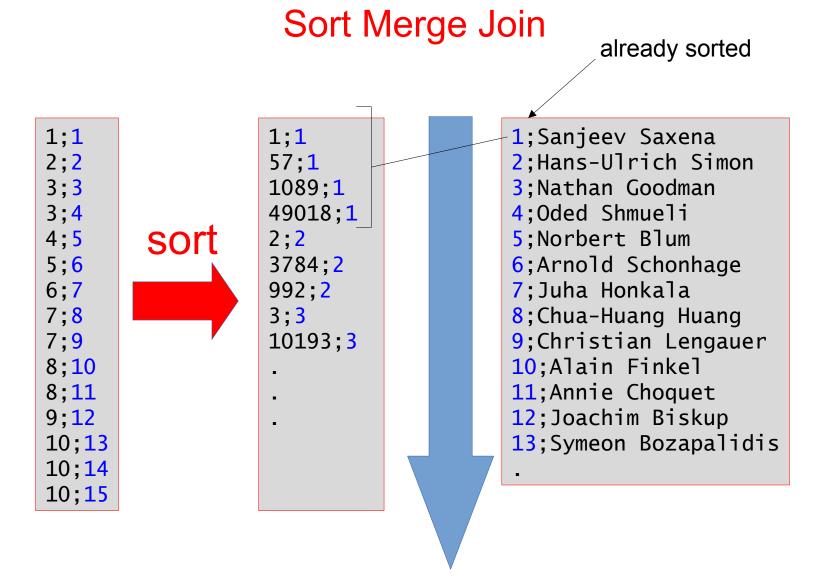

- → no full outer join in **mysql**
- → write a query that does full outer join

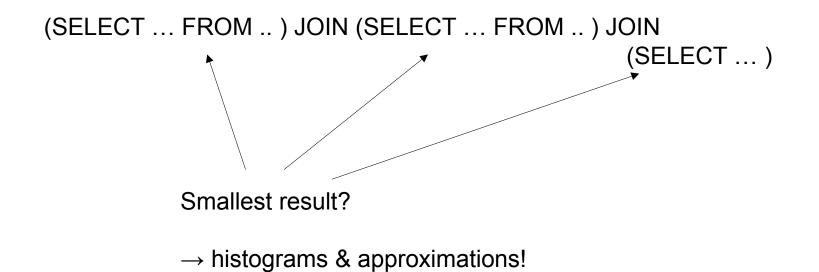

- \rightarrow outer joins can be useful to efficiently implement other queries!
- \rightarrow efficiency of joins?
 - (*) nested loop
 - (*) sort merge
 - (*) hash join
- \rightarrow intermediate result sizes can be HUGE
- → query performance often depends on how you write the query! (difficult problem)
- \rightarrow create indexes on all columns on which you join!

pick up join results in one top-down traversal on both tables

Sort Merge Join

- → a B-tree index is nothing else but a SORTED search-tree that behaves well on disk
- → even having such sorted **B-tree indexes**, efficient join processing remains a tremendous challenge
 - E.g. how to **pick best order**, in which to apply joins?

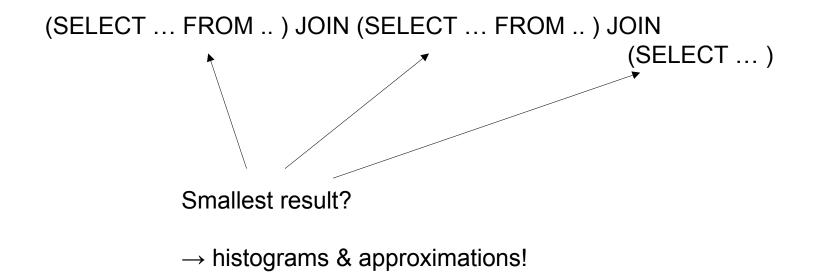

Sort Order

 \rightarrow can cause the query to run

few seconds, or a day ...

 \rightarrow absolutely crucial to determine good join order!

In a graph, determine if two given nodes A,B are connected.

In a graph, determine if two given nodes A,B are connected.

What we can do in SQL:

1) determine all nodes at distance 1 from A:

(SELECT cid FROM CA WHERE aid=A) = CA0

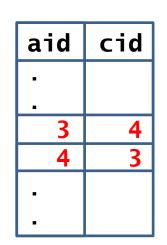

2) apply to this set of nodes the same query

SELECT cid FROM CA WHERE aid IN CA0 - { A }; (= CA1)

This determines all nodes at distance two.

3) SELECT aid IN CA1 – CA0;

 \rightarrow after **k** such queries we have nodes at distance **k**.

On the given Co-Author Graph CA (1.6 million nodes, 6.7 million edges) this is feasible.

 \rightarrow for ONE AUTHOR, and takes about 5 minutes (on a laptop)

But, find distance for EVERY PAIR OF AUTHORS is infeasible.

1.6 million authors.

1.6 * 1.6 million numbers to compute. Storage: 2.5 TB

(probably takes years to compute)

SELECT 1.0*COUNT(*)/(2* (SELECT COUNT(distinct aid) from CA)); 4.37035511508065

- $\rightarrow~$ distance for EVERY PAIR OF AUTHORS
- \rightarrow is between 0 and 15.

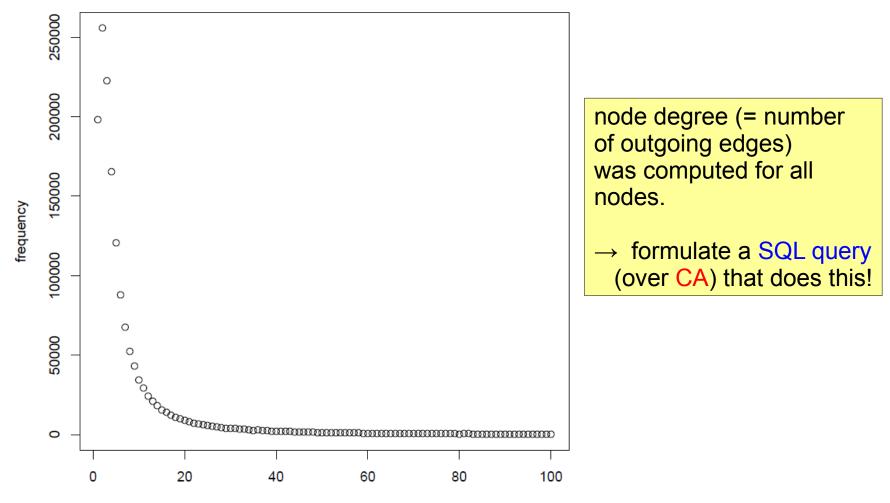

Degree Distribution? \rightarrow follows a POWER LAW! (such as Zipf Distribution!)

Average?

Mean / mode?

Power Law

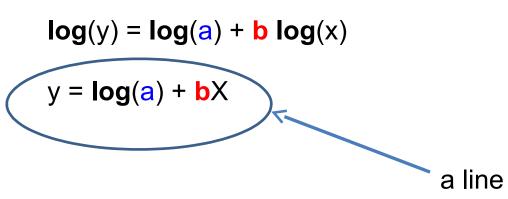

Degree Distribution of CA-Graph

degree

Power Law

 $y = ax^{b}$

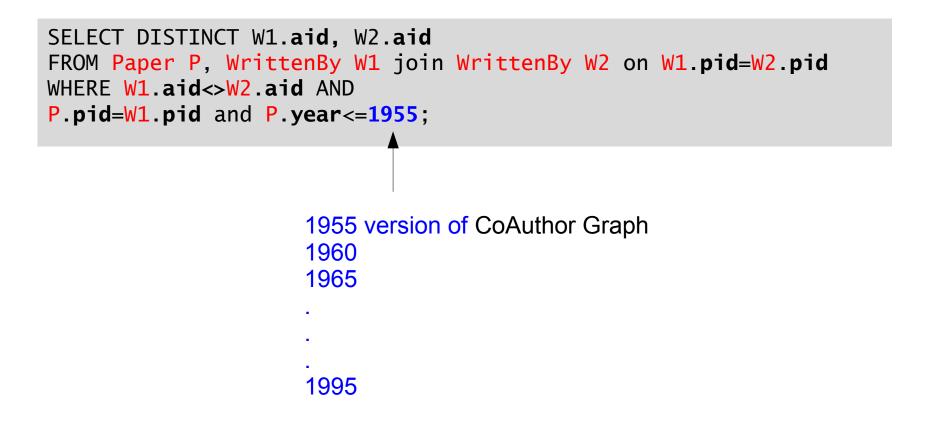

e.g., typical Zipf could be: N N/2 N/3 N/4 N/5 N/6 . . . (a = 1, b = -1)

Small World

"I read somewhere that everybody on this planet is separated by only six other people. Six degrees of separation. Between us and everybody else on this planet. The president of the United States. A gondolier in Venice. fill in the names. I find that A) tremendously comforting that we're so close and B) like Chinese water torture that we're so close. Because you have to find the right six people to make the connection. It's not just big names. It's anyone. A native in a rain forest. A Tierra del Fuegan. An Eskimo. I am bound to everyone on this planet by a trail of six people. It's a profound thought. How Paul found us. How to find the man whose son he pretends to be. Or perhaps is his son, although I doubt it. How every person is a new door, opening up into other worlds. Six degrees of separation between me and everyone else on this planet. But to find the right six people."

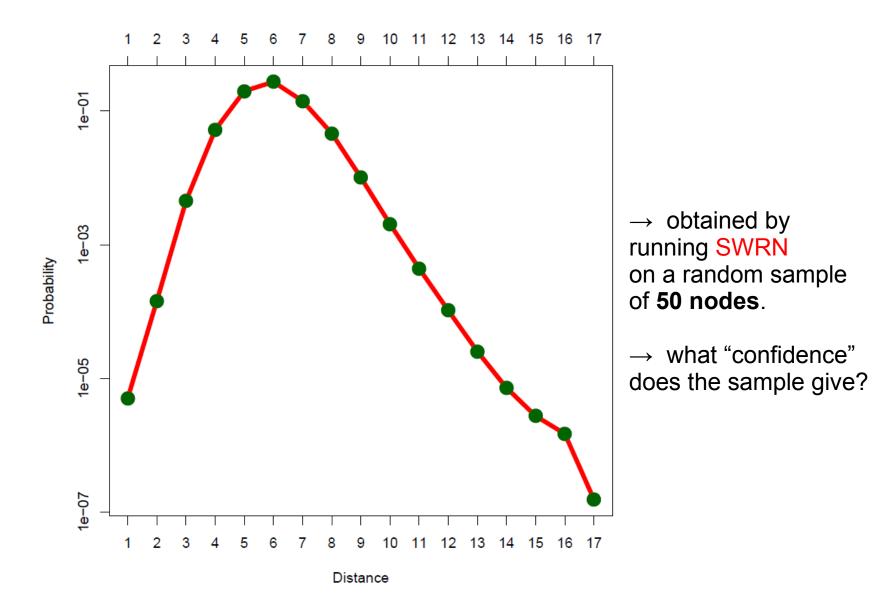

John Guare
