

## System 1 Overview

How to discriminate between and also estimate image positions?

*vs*

Geometric Model-based Object Recognition

## System 1 Overview

### Geometric Model-based Object Recognition

**This Lecture:** Geometric description

**Next Lecture:** Model matching

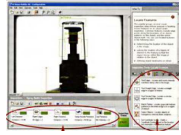

Pose estimation

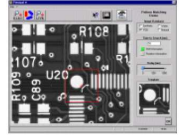

Verification

## Motivation - automated visual inspection

Manufacturing

- High speed product verification
- Largest use of computer vision systems worldwide
- Most western manufacturing has some visual quality control

## Introduction

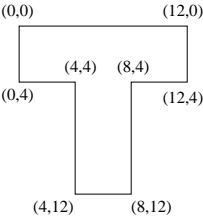

Given:

Isolated binary image object

Assume:

1. Geometric shape models for parts to be recognized

## 2. Image feature positions

System does:

1. Matches image and model features
2. Estimates transformation mapping model onto data

## Data Description

Goal: describe parts in same vocabulary of boundary shapes as model

- Get object pixels that lie on the boundary
- Split pixels into straight line sets
- Find corners where the lines meet  
(Here we ignore curved boundaries.)

## Boundary Finding

1) Get points that lie on boundary:

```
[r,c] = find( bwperim(Image,4) == 1 )
```

2) Remove any spurs on boundary, track and segment

```
[sr,sc] = removespurs(r,c,H,W);

```

## Removing Dangling Spurs

Spur: any boundary pixel with only 1 neighbor inside a 3x3 neighborhood

```

changed=1;
while changed==1
    changed = 0;
    [sr,sc] = find(work==1);    % work: boundary pixels
    for i = 1 : length(sr)    % check each boundary point
        neigh = work(sr(i)-1:sr(i)+1,sc(i)-1:sc(i)+1);
        count=sum(sum(neigh));
        if count < 3          % only point and at most
            work(sr(i),sc(i)) = 0; % 1 neighbor so remove it
            changed=1;
    end
end
    
```

Trailing ends omitted.

AV: 2D Geometric vision

Fisher lecture 2 slide 9

## Removing Unnecessary Boundary Pixels

Find unnecessary corners:

\* - boundary point to keep

c - boundary point to remove

? - boundary point thru here somehow

shaded box - interior or exterior pixel

thick red box - pixel neighbourhood inspected

AV: 2D Geometric vision

Fisher lecture 2 slide 10

## Boundary Cleaning Results

Raw boundary:

AV: 2D Geometric vision

Fisher lecture 2 slide 11

Cleaned boundary:

AV: 2D Geometric vision

Fisher lecture 2 slide 12

## Getting a Consecutive Boundary Track

TRACK TO FIRST  
UNTRACKED BOUNDARY  
PIXEL ENCOUNTERED  
AS  $i$  GOES 1...7

NEXT DIRECTIONS

1	2	3
8	x	4
7	6	5

$$\text{NEXT} = (\text{LAST} + 3 + i) \text{ MOD } 8 + 1$$

EXAMPLE TRACKING

LAST MOVE = 3  
NEXT MOVE = 8,1,2,3,4,5,6

## Tracking Results

Despurred boundary (unorganized point set):

Tracked boundary (consecutive point set):

## Midlecture Problem

Given the following tracking sequence:

What is the order of pixels to be considered for tracking to the next pixel?

## Recursive splitting the boundary into linear segments

1. Find leftmost point A
2. Find rightmost point B
3. Split points in set  $A \rightarrow B$  and  $B \rightarrow A$ :
  - (a) Find line thru current segment endpoints X & Y
  - (b) Find point Z furthest from the line at distance d
  - (c) If d is less than a threshold, then this segment finished
  - (d) Otherwise, create new sets  $X \rightarrow Z$  and  $Z \rightarrow Y$  and recurse

## Recursive Splitting Algorithm

AV: 2D Geometric vision

Fisher lecture 2 slide 17

## Recursive Splitting Code

```
function recsplit(r,c,threshold)
    global numlines lines
    n = length(r);           % total number of points
    vec = [c(n)-c(1), r(1)-r(n)]; % unit vector
    vec = vec/norm(vec);     % perpendicular to XY

    % find point furthest from line
    maxdist = 0;
    for i = 1 : n
        dist = abs( [r(i) - r(1), c(i) - c(1)] * vec' );
        if dist > maxdist
            maxdist = dist;
            maxindex = i;           % where furthest
        end
    end
end
```

AV: 2D Geometric vision

Fisher lecture 2 slide 18

```
% check for splitting by testing maximum point distance
if maxdist < threshold
    % then it's a single line - save it
    numlines = numlines + 1;
    lines(numlines,1) = r(1);
    lines(numlines,2) = c(1);
    lines(numlines,3) = r(n);
    lines(numlines,4) = c(n);
else
    % otherwise it needs to be split up
    recsplit(r(1:maxindex),c(1:maxindex),threshold);
    recsplit(r(maxindex:n),c(maxindex:n),threshold);
end
```

Fisher lecture 2 slide 20

## Describing Lines

Endpoints	Length	True Length
(249,123)-(261,127)	13	-
(261,127)-(373,289)	197	247
(373,289)-(390,316)	32	-
(390,316)-(388,330)	14	-
(388,330)-(85,536)	366	371
(85,536)-(13,437)	122	124
(13,437)-(250,268)	291	294
(250,268)-(186,171)	116	124
(186,171)-(249,123)	79	77

Input into matcher: extra lines, short lines, longer lines

## Full Result Set

## Running Program

```
>> doall
Input model to image scale factor (float)
?30.9
Want to use live test data (0,1)
?0
Test image file stem (filestem)
?TESTDATA1/f

initial_split =

    108    177    219    607

numlines =

    10
```

```
ans =

    108    177    291    331
    ...
    21    275    108    177

Want to process another image 2 (0,1)
?1
```

## Discussion

1. Simple boundary track and segment process
2. Gives compact line-based description
3. May have some extra segments
4. Segments may be too long or short
5. Description is input into matcher

## What Have We Learned?

Introduction to

- Data cleaning
- Boundary/Curve tracking
- Curve segmentation

From pixels to descriptions

Next: Matching descriptions to models
