Improving Performance: Pipelining

IF    Instruction Fetch (includes PC increment)
ID    Instruction Decode + fetching values from general purpose registers
EXE   Execute arithmetic/logic operations or address computation
MEM   Memory access or branch completion
WB    Write Back results to general purpose registers (a.k.a. Commit)
Phases of Instruction Execution

- **Instruction Fetch**
  - InstructionRegister = MemRead (INST_MEM, PC)

- **Decoding**
  - Generate datapath control signals
  - Determine register operands

- **Operand Assembly**
  - Trivial for some ISAs, not for others
  - E.g. select between literal or register operand; operand pre-scaling
  - Sometimes considered to be part of the Decode phase

- **Function Evaluation or Address Calculation**
  - Add, subtract, shift, logical, etc.
  - Address calculation is simply unsigned addition

- **Memory Access (if required)**
  - Load: ReadData = MemRead(DATA_MEM, MemAddress, Size)
  - Store: MemWrite (DATA_MEM, MemAddress, WriteData, Size)

- **Completion**
  - Update processor state modified by this instruction
  - Interrupts or exceptions may prevent state update from taking place

*Note: INST_MEM and DATA_MEM may be same or separate physical memories*
Instruction fetch

- Read from Instruction Cache at address given by PC
- Increment PC, i.e. PC = PC + sizeof(instruction)
MIPS R-type instruction format

6 bits  5 bits  5 bits  5 bits  5 bits  6 bits
opcode   reg  rs  reg  rt  reg  rd  shamt  funct

Destination register for R-type format

<table>
<thead>
<tr>
<th>add</th>
<th>$1, $2, $3</th>
</tr>
</thead>
<tbody>
<tr>
<td>sll</td>
<td>$4, $5, 16</td>
</tr>
</tbody>
</table>

<table>

<th>5 bits</th>
<th>5 bits</th>
<th>16 bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>opcode</td>
<td>reg rs</td>
<td>reg rt</td>
<td>immediate value/addr</td>
</tr>
</tbody>
</table>

Destination register for Load

- `lw $1, offset($2)`
- `beq $4, $5, .Label1`
- `addi $1, $2, -10`

<table>
<thead>
<tr>
<th>lw</th>
<th>$2</th>
<th>$1</th>
<th>address offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>beq</td>
<td>$4</td>
<td>$5</td>
<td>(PC - .Label1) &gt;&gt; 2</td>
</tr>
<tr>
<td>addi</td>
<td>$2</td>
<td>$1</td>
<td>0xffffffff</td>
</tr>
</tbody>
</table>

Inf3 Computer Architecture - 2015-2016
Reading Registers

- Use source register fields to address the register file and read two registers
- Select the destination register address, according to the format

```
PC
```

![Diagram showing the process of reading registers from instruction memory and writing to the register file.](Diagram.png)
Extracting the literal operand

- Sign-extend the 16-bit literal field, for those instructions that have a literal

```verilog
lit = { {16{inst[15]}}, inst[15:0] }
```
Performing the Arithmetic

- Perform arithmetic or logical operation on Read Data 0 and either Read Data 1 or the sign-extended literal
Inside the ALU

- Adder, Logic Unit, and Barrel Shifter are separate combinational logic blocks
Computing Branch Displacements

- Compute sum of PC and scaled, sign-extended literal displacement
- Can’t share ALU, it might be needed for comparisons during branch operations
Accessing Memory – Loads & Stores

- Load and Store instructions use the ALU result as the effective address
- Store instructions use Read Data 1 as the store data
Decoding Instructions

- Control signals driven by combinational logic, based on instruction opcode
Pipelined Instruction Execution

CPU Pipeline Structure
Implementation Issues: Pipeline balance

- Each pipeline stage is a combinational logic network
  - Registered inputs and outputs
  - Longest circuit delay through all stages determines clock period

Ideally, all delays through every pipeline stage are identical

In practice this is hard to achieve
Representing a sequence of instructions

- Space-time diagram of pipeline
- Think of each instruction as a time-shifted pipeline
Information flow constraints

- Information from one instruction to any successor must always move from left to right
Another way to represent pipeline timing

- A similar, and slightly simpler, way to represent pipeline timing:
  - Clock cycles progress left to right
  - Instructions progress top to bottom
  - Time at which each instruction is present in each pipeline stage is shown by labelling appropriate cell with pipeline name

- This form is used in H&P, and throughout the remainder of these notes.

Pipeline Hazards

- Hazards are pipeline events that restrict the pipeline flow
- They occur in circumstances where two or more activities cannot proceed in parallel
- There are three types of hazard:
  - **Structural Hazards**
    - Arise from resource conflicts, when a set of actions have to be performed sequentially because there is not sufficient resource to operate in parallel
  - **Data Hazards**
    - Occur when one instruction depends on the result of a previous instruction, and that result is not yet available. These hazards are exposed by the overlapped execution of instructions in a pipeline
  - **Control Hazards**
    - These arise from the pipelining of branch instructions, and other activities that change the PC.
Structural Hazards

- Multi-cycle operations
- Memory or register file port restrictions

Example structural hazard caused by having only one memory port

<table>
<thead>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Data Hazards

- Overlapped execution of instructions means information may be required before it is available.
Data hazards lead to pipeline stalls

- SUB instruction must wait until R1 has been written to register file
- All subsequent instructions are similarly delayed
Minimising data hazards by data-forwarding

- Key idea is to bypass the register file and forward information, as soon as it becomes available within the pipeline, to the place it is needed.

```
ADD R1, R2, R3
SUB R4, R1, R5
AND R6, R1, r7
OR R8, r1, R9
XOR R10, R1, R11
```
CPU pipeline showing forwarding paths
Data hazards requiring a stall

- Hazards involving the use of a Load result usually require a stall, even if forwarding is implemented
Hazes involving the use of a Load may be avoided by reordering the code.

```
LW R1, 2(R2)
LW R3, 4(R1)
ADD R4, R4, R3
ADD R1, R1, 4
SUB R9, R9, 1
```
Code scheduling to avoid stalls (after)

- SUB is entirely independent of other instructions – place after 1st load
- ADD to R1 can be placed after LW to R3 to hide the load delay on R3
General Performance Impact of Hazards

Speedup from pipelining: \[ S = \frac{CPI_{\text{unpipelined}}}{CPI_{\text{pipelined}}} \times \frac{\text{clock}_{\text{unpipelined}}}{\text{clock}_{\text{pipelined}}} \]

\( CPI_{\text{pipelined}} = \text{ideal CPI} + \text{stall cycles per instruction} = 1 + \text{stall cycles per instruction} \)

\( CPI_{\text{unpipelined}} \sim \text{pipeline depth} \)

\( \frac{\text{clock}_{\text{unpipelined}}}{\text{clock}_{\text{pipelined}}} \sim 1 \)

\[ S = \frac{\text{pipeline depth}}{1 + \text{stall cycles per instruction}} \]
Control Hazards

- When a branch is executed, PC is not affected until the branch instruction reaches the MEM stage.
- By this time 3 instructions have been fetched from the fall-through path.

```
BEQZ R1, label
SUB R4, R2, R5
AND R6, R2, r7
OR R8, r2, R9
: label:
XOR R10, R1, R11
```
Effect of branch penalty on CPI

- In this example pipeline the cost of each branch is:
  - 1 cycle, if the branch is not taken (due to load-delay slot)
  - 4 cycles, if the branch is taken

- If an equal number of branches are taken and not taken, and if 20% of all instructions are branches (a reasonable assumption), then
  - \[ \text{CPI} = 0.8 + 0.2 \times 2.5 = 1.3 \]
  - This is a significant reduction in performance

- If the pipeline was deeper, with 2 stages for ALU and 2 stages for Decode, then:
  - Cost of taken branch would be 6 cycles
  - \[ \text{CPI} = 0.8 + 0.2 \times 3.5 = 1.5 \]

- Deeper pipelines have greater branch penalties, and potentially higher CPI
- Pentium 4 (Prescott) had 31 pipeline stages! (this was too deep)
- Several important techniques have been developed to reduce branch penalties
  - Early branch outcome
  - Delayed branches
  - Branch prediction (static and dynamic)
Early branch outcome calculation - BEQZ, BNEZ
Delayed branch execution

- Always execute the instruction immediately after the branch, regardless of branch outcome.

**Before**: instruction after the branch gets killed if the branch is taken.

**After**: by moving the SUB instruction into the branch delay slot, and executing it unconditionally, the 1-cycle penalty is eliminated.
Impact of Empty Load-delay Slots on CPI

Bottom-line: CPI increase of 0.01 – 0.27 cycles
Impact of Branch Hazards on CPI

Bottom-line: CPI increase of 0.06 – 0.62 cycles
