## Overview

- 1 Basics
- 2 Linear Algebra Operations
- 3 Useful Operations
- 4 Quiz
- 5 Vectorising

## Overview

A MATLAB vector is a one-dimensional array of the same type:

### Vector Examples

<code>[3 9 6]</code>	Three integer elements
<code>[]</code>	No elements
<code>[1.2 0.3]</code>	Two real number elements

(There are no differences between vectors and matrices, apart from the dimensions)

Vectors are created either as a by-product of some operation or directly:

### Vector Creation

```
a = [3 9 6] %Creates a vector called a
b = a * 3 %Creates a new vector
```

Note that there is no need to specify the size of the vector.

## Overview

Individual components are accessed using indexing:

### Vector Creation

```
a = [3 9 6] %Creates a vector called a
c = a(1)   % Select the first element
```

- Round-brackets are used to specify an entry.
- Indexing starts from 1 (not zero).

## Overview

Sequence components are specified using the colon notation:

### Vector Creation

```
a = [3 9 6] %Creates a vector called a
c = a(1:2) % Create the vector [3 9]
```

## Overview

Items can be directly replaced:

### Vector Creation

```
a = [3 9 6] %Creates a vector called a
a(2) = 8    % Create the vector [3 8 6]
a(5) = 1    % Create the longer vector [3 8 6 0 1]
```

Note: implied entries are set to zero.

## Linear Algebra Operations

MATLAB directly supports common operations:

### Linear Algebra Examples

```
norm(a)           % Find the norm (length) of a
dot(a, b)         % Dot product of a and b
a * 4             % Scalar multiplication
a - b            % Vector subtraction
a + b            % Vector addition
a / norm(a)       % Create a unit vector
dot(a,b) / (norm(a) * norm(b)) % Cosine angle
```

## Useful Operations

MATLAB has a library with many common operations:

### Useful Operations

```
sum(a)       $\sum_{i=1}^n a_i$ 
prod(a)      $\prod_{i=1}^n a_i$ 
sort(a)     % Sort the vector
max(a)      % Find the largest element
min(a)      % Find the smallest element
length(a)   %How many elements in the vector
```

In general, before writing some code, see if MATLAB already supports it!

## Quiz

A *stack* is a data structure supporting the following operations:

- Push: add an element to a list (eg `push(a,(b c)) = (a b c)`).
- Pop: remove the first element from the list (eg `pop((a b c)) = (b c)`)

How can MATLAB implement these operations?

## Vectorising

- MATLAB is a general-purpose programming language
- It also has efficient support for common operations over vectors.
- *Vectorising* means using these operations in place of explicit control constructs.

## Vectorising : An Example

- *Logical* indexing uses a vector to specify whether a corresponding component in another vector should be extracted.
- A one in that vector means extract the corresponding element (and a zero means ignore it).

### Logical Indexing

```
a = [1 2 3]
b = [0 1 1]
a(logical(b)) = [2 3]
```

## Vectorising : Another example

- The operation `>` tests whether each element in a vector is greater than some number.
- Likewise, the operation `<` tests whether each element in a vector is less than some number.
- How can we use vectorising to remove numbers which fall outside of some range?

### Trimming bad values

```
a = [-999 2 3 3 999]
b = a > 0 & a < 5
a(logical(b)) = [2 3 3]
```

## Summary

- Vectors in MATLAB are first-class types.
- There are a rich variety of operations over them.
- Vectorising is a technique for writing faster, more compact programs.

## Vectorising : Another example

- The operation `==` tests whether each element in a vector is equal to some number.
- How can we use vectorising to count the number of components that are equal to some number?

### Trimming bad values

```
a = [-999 2 3 3 999]
sum((a == 3)) = 2
```

Note: this does not use *logical indexing*, we simply count the number of true elements in the logical vector.
