Features

POS tagging tools

• Three commonly used, freely available tools for tagging:

http://www.cs.jhu.edu/~brill/

- InT by Thorsten Brants (2000): Hidden Markov Model

http://www.coli.uni-saarland.de/ thorsten/tnt/
- Brill tagger by Eric Brill (1995): transformation based learning

- MXPOST by Adwait Ratnaparkhi (1996): maximum entropy model

ftp://ftp.cis.upenn.edu/pub/adwait/jmx/jmx.tar.gz

• All have similar performance (~96% on Penn Treebank English)

- Each tagging decision for a word occurs in a specific context
- \bullet For tagging, we consider as context the **history** h_i
 - the word itself
 - morphological properties of the word
 - other words surrounding the word
 - previous tags
- \bullet We can define a feature f_j that allows us to learn how well a specific aspect of histories h_i is associated with a tag t_i

PK DIL 2 February 2006

= informatics

Features (3)

• In a maximum entropy model, this information is captured by a feature

$$f_j(h_i,t_i) = \begin{cases} 1 & \text{if } w_i = like \text{ and } t_i = VB \\ 0 & \text{otherwise} \end{cases}$$

• The importance of a feature f_i is defined by a parameter λ_i

Features in Ratnaparkhi [1996]

i eatures	iii Katilaparkiii [1990]
frequent w_i	$w_i = X$
rare w_i	X is prefix of w_i , $ X \le 4$ X is suffix of w_i , $ X \le 4$
	$ X $ is suffix of w_i , $ X \leq 4$
	w_i contains a number
	w_i contains uppercase character
	w_i contains hyphen
all w_i	$t_{i-1} = X$ $t_{i-2}t_{i-1} = XY$
	$t_{i-2}t_{i-1} = XY$

 $\begin{aligned} w_i & t_{i-1} = X \\ t_{i-2}t_{i-1} = XY \\ w_{i-1} = X \\ w_{i-2} = X \\ w_{i+1} = X \\ w_{i+2} = X \end{aligned}$

nformatics

Probabilities vs. rules

- We examined two supervised learning methods for the tagging task
- HMMs: probabilities allow for graded decisions, instead of just yes/no
- Transformation based learning: more features can be considered
- We would like to combine both ⇒ maximum entropy models
 - a large number of features can be defined
 - features are weighted by their importance

DV DII 2 Fabruary 201

nformatics

Features (2)

• We observe in the data patterns such as:

the word like has in 50% of the cases the tag VB

 Previously, in HMM models, this led us to introduce probabilities (as part of the tag sequence model) such as

$$p(VB|like) = 0.5$$

PK DIL 2 February 20

anformatics

Features (4)

• Features may consider morphology

$$f_j(h_i,t_i) = \begin{cases} 1 & \text{if suffix}(w_i) = \text{"ing" and } t_i = VB \\ 0 & \text{otherwise} \end{cases}$$

• Features may consider tag sequences

$$f_j(h_i,t_i) = \begin{cases} 1 & \text{if } t_{i-2} = DET \text{ and } t_{i-1} = NN \text{ and } t_i = VB \\ 0 & \text{otherwise} \end{cases}$$

 h_i and a tag t_i

Log-linear model

ullet Features f_j and parameters λ_j are used to compute the probability $p(h_i,t_i)$:

$$p(h_i, t_i) = \prod_{f_i} \lambda_j^{f_j(h_i, t_i)}$$

- $\overline{f_j}$ These types of models are called log-linear models, since they can be reformulated into
- There are many learning methods for these models, maximum entropy is just

Questions for training

Conditional probabilities

ullet We defined a model $p(h_i,t_i)$ for the joint probability distribution for a history

 $p(h_i|t_i) = \frac{p(h_i, t_i)}{\sum_{i'} p(h_i, t_{i'})}$

• Conditional probabilities can be computed straight-forward by

Feature selection

- given the large number of possible features, which ones will be part of the model?
- we do not want redundant features
- we do not want unreliable and rarely occurring features (avoid overfitting)
- Parameter values λ_j
 - λ_j are positive real numbered values
- how do we set them?

13 Informatics

Setting the parameter values λ_i : Goals

ullet The empirical expectation of a feature f_j occurring in the training data is defined by

$$\bar{E}(f_j) = \frac{1}{n} \sum_{i=1}^{n} f_j(h_i, t_i)$$

• The model expectation of that feature occurring is

$$E(f_j) = \sum_{h,t} p(h,t) f_j(h,t)$$

• We require that $\bar{E}(f_j) = E(f_j)$

f informatics

2 February 2006

Model expectation

• We defined the model expectation of a feature occurring as

$$E(f_j) = \sum_{h,t} p(h,t) f_j(h,t)$$

- ullet Practically, we cannot sum over all possible histories h and tags t
- Instead, we compute the model expectation of the feature on the training data

$$E(f_j) \approx \frac{1}{n} \sum_{i=1}^{n} p(t|h_i) \ f_j(h_i, t)$$

Note: theoretically we have to sum over all t, but $f_j(h_i,t)=0$ for all but one t

$$\log p(h_i, t_i) = \sum_{f_j} f_j(h_i, t_i) \log \lambda_j$$

- one of them

Tagging a sequence

- This can be decomposed into:

ullet We want to tag a sequence $w_1,...,w_n$

$$p(t_1,...,t_n|w_1,...,w_n) = \prod_{i=1}^n p(t_i|h_i)$$

- ullet The history h_i consist of all words $w_1,...,w_n$ and previous tags $t_1,...,t_{i-1}$
- We cannot use Viterbi search \Rightarrow heuristic beam search is used (more on beam search in a future lecture on machine translation)

2 February 2006

12 Informatics

nf School of tics

1nformatics

Feature selection

- Feature selection in Ratnaparkhi [1996]
 - Feature has to occur 10 times in the training data
- Other feature selection methods
 - use features with high mutual information
 - add feature that reduces training error most, retrain

2 February 2006

Empirical expectation

• Consider the feature

$$f_j(h_i,t_i) = egin{cases} 1 & ext{if } w_i = like ext{ and } t_i = VB \ 0 & ext{otherwise} \end{cases}$$

- ullet Computing the empirical expectation $ar{E}(f_j)$:
 - if there are 10,000 words (and tags) in the training data
 - and the word like occurs with the tag VB 20 times

$$\bar{E}(f_j) = \frac{1}{n} \sum_{i=1}^{n} f_j(h_i, t_i) = \frac{1}{10000} \sum_{i=1}^{10000} f_j(h_i, t_i) = \frac{20}{10000} = 0.002$$

2 February 2006

16 informatics

Goals of maximum entropy training

ullet *Recap:* we require that $ar{E}(f_j)=E(f_j)$, or

$$\frac{1}{n} \sum_{i=1}^n f_j(h_i, t_i) = \frac{1}{n} \sum_{i=1}^n p(t|h_i) \ f_j(h_i, t)$$

- Otherwise we want maximum entropy, i.e. we do not want to introduce any additional order into the model (Occam's razor: simplest model is best)
- Entropy:

$$H(p) = \sum_{h,t} p(h,t) \log p(h,t)$$

2 February 2006

17 informatics

Improved Iterative Scaling [Berger, 1993]

 $\begin{array}{l} \textit{Input:} \ \ \text{Feature functions} \ f_1,...,f_m, \ \text{empirical distribution} \ \bar{p}(x,y) \\ \textit{Output:} \ \ \text{Optimal parameter values} \ \lambda_1,...,\lambda_m \end{array}$

- 1. Start with $\lambda_i=0$ for all $i\in\{1,2,...,n\}$
- 2. Do for each $i \in \{1,2,...,n\}$:

a.
$$\Delta \lambda_i = \frac{1}{C} \log \frac{\tilde{E}(f_i)}{E(f_i)}$$

b. Update $\lambda_i \leftarrow \lambda_i + \Delta \lambda_i$

b Update
$$\lambda_i \leftarrow \lambda_i + \Delta \lambda_i$$

3. Go to step 2 if not all the λ_i have converged

Note: This algorithm requires that $\forall t,h:\sum_i f_i(t,h)=C$, which can be ensured with an additional filler feature
