# What is part of speech tagging?

# Foundations of Natural Language Processing Lecture 8 Part-of-speech Tagging and HMMs

Shay Cohen (based on slides by Henry Thompson, Alex Lascarides, Sharon Goldwater & Philipp Koehn)

7 February 2020

• Given a string:

Henry S. Thompson

This is a simple sentence

• Identify parts of speech (syntactic categories):

This/DET is/VB a/DET simple/ADJ sentence/NOUN

# informatics

Henry S. Thompson

FNLP Lecture 8

7 February 2020

# Why do we care about POS tagging?

- POS tagging is a first step towards syntactic analysis (which in turn, is often useful for semantic analysis).
  - Simpler models and often faster than full parsing, but sometimes enough to be useful.
  - For example, POS tags can be useful features in text classification (see previous lecture) or word sense disambiguation (see later in course).
- Illustrates the use of hidden Markov models (HMMs), which are also used for many other tagging (sequence labelling) tasks.

# Examples of other tagging tasks

FNLP Lecture 8

• Named entity recognition: e.g., label words as belonging to persons, organizations, locations, or none of the above:

Barack/PER Obama/PER spoke/NON from/NON the/NON White/LOC House/LOC today/NON ./NON

• Information field segmentation: Given specific type of text (classified advert, bibiography entry), identify which words belong to which "fields" (price/size/location, author/title/year)

3BR/SIZE flat/TYPE in/NON Bruntsfield/LOC ,/NON near/LOC main/LOC roads/LOC ./NON Bright/FEAT ,/NON well/FEAT maintained/FEAT ...

#### Sequence labelling: key features

In all of these tasks, deciding the correct label depends on

- the word to be labeled
  - NER: Smith is probably a person.
  - POS tagging: chair is probably a noun.
    - $\ast$  but it could be a verb
- the labels of surrounding words
  - NER: if following word is an organization (say Corp.), then this word is more likely to be organization too.
  - POS tagging: if preceding word is a modal verb (say will) then this word is more likely to be a verb.

HMM combines these sources of information probabilistically.

Henry S. Thompson

FNLP Lecture 8

#### How many parts of speech?

- Both linguistic and practical considerations
- Corpus annotators decide. Distinguish between
  - proper nouns (names) and common nouns?
  - singular and plural nouns?
  - past and present tense verbs?
  - auxiliary and main verbs?
  - etc
- Commonly used tagsets for English usually have 40-100 tags. For example, the Penn Treebank has 45 tags.

# Parts of Speech: reminder

- Open class words (or content words)
  - nouns, verbs, adjectives, adverbs
  - mostly content-bearing: they refer to objects, actions, and features in the world
  - open class, since there is no limit to what these words are, new ones are added all the time (selfie, Brexit, omnishambles).
- Closed class words (or function words)
  - pronouns, determiners, prepositions, connectives, ...
  - there are a limited number of these
  - mostly functional: to tie the concepts of a sentence together
  - new ones are rare:
    - $\ast\,$  So far none of the attempts to introduce new gender-neutral pronouns have gotten much traction
    - $\ast\,$  The only other example I'm aware is the use of real as an intensifier (older ones include very, slightly, too)
- Henry S. Thompson

J&M Fig 5.6: Penn Treebank POS tags

Δ

### **POS** tags in other languages

Morphologically rich languages often have compound morphosyntactic tags

Noun+A3sg+P2sg+Nom (J&M3, Chapter 10.7)

- Hundreds or thousands of possible combinations
- Predicting these requires more complex methods than what we will discuss (e.g., may combine an FST with a probabilistic disambiguation system)

# Why is POS tagging hard?

The usual reasons!

#### Ambiguity:

glass of water/NOUN vs. water/VERB the plants lie/VERB down vs. tell a lie/NOUN vs. a mighty wind/NOUN wind/VERB down

(homographs)

How about time flies like an arrow?

• Sparse data:

Henry S. Thompson

- Words we haven't seen before (at all, or in this context)
- Word-Tag pairs we haven't seen before (e.g., if we verb a noun)

Henry S. Thompson

FNLP Lecture 8

# Relevant knowledge for POS tagging

Remember, we want a model that decides tags based on

- The word itself
  - Some words may only be nouns, e.g. arrow
  - Some words are ambiguous, e.g. like, flies
  - Probabilities may help, if one tag is more likely than another
- Tags of surrounding words
  - two determiners rarely follow each other
  - two base form verbs rarely follow each other
  - determiner is almost always followed by adjective or noun

# A probabilistic model for tagging

FNLP Lecture 8

To incorporate these sources of information, we imagine that the sentences we observe were generated probabilistically as follows.

• To generate sentence of length *n*:

Let  $t_0 = <s>$ For i = 1 to nChoose a tag conditioned on previous tag:  $P(t_i|t_{i-1})$ Choose a word conditioned on its tag:  $P(w_i|t_i)$ 

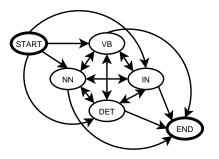

- So, the model assumes:
  - Each tag depends only on previous tag: a bigram tag model.
  - Words are independent given tags

8

q

#### Probabilistic finite-state machine

• One way to view the model: sentences are generated by walking through **states** in a graph. Each state represents a tag.

• Prob of moving from state s to s' (transition probability):  $P(t_i = s' | t_{i-1} = s)$ 

FNLP Lecture 8

#### **Example transition probabilities**

$t_{i-1} \setminus t_i$	NNP	MD	VB	IJ	NN	
<s></s>	0.2767	0.0006	0.0031	0.0453	0.0449	
NNP	0.3777	0.0110	0.0009	0.0084	0.0584	
MD	0.0008	0.0002	0.7968	0.0005	0.0008	
VB	0.0322	0.0005	0.0050	0.0837	0.0615	
JJ	0.0306	0.0004	0.0001	0.0733	0.4509	

• Probabilities estimated from tagged WSJ corpus, showing, e.g.:

- Proper nouns (NNP) often begin sentences:  $P(NNP|<s>) \approx 0.28$
- Modal verbs (MD) nearly always followed by bare verbs (VB).
- Adjectives (JJ) are often followed by nouns (NN).

Table excerpted from J&M draft 3rd edition, Fig 8.5

Henry S. Thompson

FNLP Lecture 8

13

#### Example transition probabilities

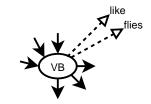

$t_{i-1} \setminus t_i$	NNP	MD	VB	IJ	NN	
<s></s>	0.2767	0.0006	0.0031	0.0453	0.0449	
NNP	0.3777	0.0110	0.0009	0.0084	0.0584	
MD	0.0008	0.0002	0.7968	0.0005	0.0008	
VB	0.0322	0.0005	0.0050	0.0837	0.0615	
JJ	0.0306	0.0004	0.0001	0.0733	0.4509	

- This table is incomplete!
- In the full table, every row must sum up to 1 because it is a **distribution** over the next state (given previous).

Table excerpted from J&M draft 3rd edition, Fig 8.5

# Probabilistic finite-state machine: outputs

• When passing through each state, emit a word.

• Prob of emitting w from state s (emission or output probability):  $P(w_i = w | t_i = s)$ 

Henry S. Thompson

#### **Example output probabilities**

$t_i \backslash w_i$	Janet	will	back	the	
NNP	0.000032	0	0	0.000048	
MD	0	0.308431	0	0	
VB	0	0.000028	0.000672	0	
DT	0	0	0	0.506099	

- $\bullet\,$  MLE probabilities from tagged WSJ corpus, showing, e.g.:
  - 0.0032% of proper nouns are Janet: P(Janet|NNP) = 0.000032
  - About half of determiners (DT) are the.
  - *the* can also be a proper noun. (Annotation error?)
    - \* Or maybe because of e.g. "Welcome to the official website of The Beatles." ...
- $\bullet\,$  Again, in full table, rows would sum to 1.

From J&M draft 3rd edition, Fig 8.6

Henry S. Thompson

FNLP Lecture 8

# What can we do with this model?

- If we know the transition and output probabilities, we can compute the probability of a tagged sentence.
- That is,
  - suppose we have sentence  $S = w_1 \dots w_n$

and its tags  $T = t_1 \dots t_n$ .

- what is the probability that our probabilistic FSM would generate exactly that sequence of words and tags, if we stepped through at random?

• This is the joint probability 
$$P(S,T) = \prod_{i=1}^{n} P(t_i|t_{i-1})P(w_i|t_i)$$

# What can we do with this model?

- If we know the transition and output probabilities, we can compute the probability of a tagged sentence.
- That is,
  - suppose we have sentence  $S = w_1 \dots w_n$ and its tags  $T = t_1 \dots t_n$ .
  - what is the probability that our probabilistic FSM would generate exactly that sequence of words and tags, if we stepped through at random?

Henry S. Thompson

FNLP Lecture 8

17

# Example: computing joint prob. P(S,T)

What's the probability of this tagged sentence?

This/DET is/VB a/DET simple/JJ sentence/NN

# **Example: computing joint prob.** P(S,T)

What's the probability of this tagged sentence?

This/DET is/VB a/DET simple/JJ sentence/NN  $\,$ 

- First, add begin- and end-of-sentence <s> and </s>. Then:
- $p(S,T) = \prod_{i=1}^{n} P(t_i|t_{i-1})P(w_i|t_i)$ 
  - $= P(\mathsf{DET}|<\!\!\mathbf{s}\!\!>)P(\mathsf{VB}|\mathsf{DET})P(\mathsf{DET}|\mathsf{VB})P(\mathsf{JJ}|\mathsf{DET})P(\mathsf{NN}|\mathsf{JJ})P(<\!\!/\mathbf{s}\!\!>|\mathsf{NN})$  $\cdot P(\mathsf{This}|\mathsf{DET})P(\mathsf{is}|\mathsf{VB})P(\mathsf{a}|\mathsf{DET})P(\mathsf{simple}|\mathsf{JJ})P(\mathsf{sentence}|\mathsf{NN})$
- Then, plug in the probabilities we estimated from our corpus.

# But... tagging?

Normally, we want to use the model to find the best tag sequence for an *untagged* sentence.

- Thus, the name of the model: hidden Markov model
  - Markov: because of Markov independence assumption (each tag/state only depends on fixed number of previous tags/states—here, just one).
  - hidden: because at test time we only see the words/emissions; the tags/states are hidden (or latent) variables.
- FSM view: given a sequence of words, what is the most probable state path that generated them?

Henry S. Thompson

FNLP Lecture 8

21

# Hidden Markov Model (HMM)

FNLP Lecture 8

HMM is actually a very general model for sequences. Elements of an HMM:

- a set of states (here: the tags)
- a set of output symbols (here: words)
- intitial state (here: beginning of sentence)
- state transition probabilities (here:  $p(t_i|t_{i-1})$ )
- symbol emission probabilities (here:  $p(w_i|t_i)$ )

# **Relationship to previous models**

- **N-gram model**: a model for sequences that also makes a Markov assumption, but has no hidden variables.
- Naive Bayes: a model with hidden variables (the classes) but no sequential dependencies.
- HMM: a model for sequences with hidden variables.

Like many other models with hidden variables, we will use Bayes' Rule to help us infer the values of those variables.

We usually assume hidden variables *are* observed during training—annotated data In the next class, we'll discuss what to do if we don't have that training data.

Henry S. Thompson

### Formalizing the tagging problem

Find the best tag sequence T for an *untagged* sentence S:

 $\operatorname{argmax}_T p(T|S)$ 

# Formalizing the tagging problem

Find the best tag sequence T for an *untagged* sentence S:

 $\operatorname{argmax}_T p(T|S)$ 

• Bayes' rule gives us:

Henry S. Thompson

$$p(T|S) = \frac{p(S|T) \ p(T)}{p(S)}$$

• We can drop p(S) if we are only interested in  $\operatorname{argmax}_T$ :

 $\operatorname{argmax}_T p(T|S) = \operatorname{argmax}_T p(S|T) \ p(T)$ 

Henry S. Thompson FNLP Lecture 8 24

#### **Decomposing the model**

Now we need to estimate P(S|T) and P(T) (actually, their product P(S|T)P(T) = P(S,T)).

- We already defined how!
- P(T) is the probability of the state transition sequence
- Given the Markov assumption, we estimate this as

$$P(T) = \prod_{i} P(t_i|t_{i-1})$$

• P(S|T) are the emission probabilities:

$$P(S|T) = \prod_{i} P(w_i|t_i)$$

#### Search for the best tag sequence

FNLP Lecture 8

- We have defined a model, but how do we use it?
  - given: word sequence S
  - wanted: best tag sequence  $T^{\ast}$
- For any specific tag sequence T, it is easy to compute P(S,T) = P(S|T)P(T).

$$P(S|T) P(T) = \prod_{i} P(w_i|t_i) P(t_i|t_{i-1})$$

• So, can't we just enumerate all possible *T*, compute their probabilites, and choose the best one?

#### Enumeration won't work

- Suppose we have c possible tags for each of the n words in the sentence.
- How many possible tag sequences?

#### Enumeration won't work

- Suppose we have c possible tags for each of the n words in the sentence.
- How many possible tag sequences?
- There are  $c^n$  possible tag sequences: the number grows *exponentially* in the length n.
- For all but small n, too many sequences to efficiently enumerate.
- This is starting to sound familiar...

Henry S. Thompson

FNLP Lecture 8

#### The Viterbi algorithm

- As in the edit distance problem, we'll use a **dynamic programming** algorithm to solve the problem.
- The **Viterbi algorithm** finds the best tag sequence without explicitly enumerating all sequences.
- As for finding the minimum edit distance, the algorithm stores partial results in a **chart** to avoid recomputing them.
- Details next time.

#### Viterbi as a decoder

FNLP Lecture 8

The problem of finding the best tag sequence for a sentence is sometimes called **decoding**.

- Because, like spell correction etc, HMM can also be viewed as a noisy channel model.
  - Someone wants to send us a sequence of tags: P(T)
  - During encoding, "noise" converts each tag to a word:  $P(\boldsymbol{S}|\boldsymbol{T})$
  - We try to decode the observed words back to the original tags.
- In fact, *decoding* is a general term in NLP for inferring the hidden variables in a test instance (so, finding correct spelling of a misspelled word is also decoding).

28

Henry S. Thompson

# Summary

- Part-of-speech tagging is a sequence labelling task.
- HMM uses two sources of information to help resolve ambiguity in a word's POS tag:
  - The words itself
  - The tags assigned to surrounding words
- Can be viewed as a probabilistic FSM.
- Given a tagged sentence, easy to compute its probability. But finding the best tag sequence will need a clever algorithm.

FNLP Lecture 8
