The Vector Space Model of Word Meaning

Recap: Word Meaning

How do we represent the meaning of words? How is semantic knowledge organized?

- Semantic information in encoded in networks of linked nodes.
- Collins and Quillian network emphasizes hierarchical relations and cognitive economy; sentence verification times.
- Does not explain similarity and relatedness effects.
- Spreading activation model does but is difficult to falsify.
- Word meaning can be decomposed into semantic features.
- Feature-list theories account for sentence verification times by postulating that we compare lists of defining and characteristic features.

The Associationist View

The meaning of a word is defined by the way it is used (Wittgenstein, 1932).

You shall know a word by the company it keeps (Firth, 1957).

Meanings of words are determined to a large extent by their distributional patterns. (Harris, 1968).

This leads to the distributional hypothesis about word meaning:

- the context surrounding a given word provides information about its meaning;
- words are similar if they share similar linguistic contexts;
- meaning captured quantitatively in terms of simple co-occurrence statistics.

Support for Associationist View

Experimental evidence indicates that the cognitive system is sensitive to distributional information.

- Infants find word boundaries in artificial language only based on statistical regularities.
- They are also sensitive to transitional probabilities over tone sequences (Saffran et al., 1996).
- Frequency affects the sequence of acquisition for certain words. Adults tend to use basic-level nouns (e.g., *dog*) more frequently in interactions with children.

The Vector Space Model of Word Meaning

• Co-occurrence statistics influence lexical decision tasks.

Informatics 1 CG: Lecture 13

such as *the*, *of*, *although*).

Distributional Hypothesis

Distribution is represented using a context vector.

	pet	bone	fur	run	brown	screen	mouse	fetch
w ₁	1	1	1	1	1	0	0	1
<i>W</i> ₂	1	0	1	0	1	0	1	0
W3	0	1	1	1	1	0	0	1

- Target words $w_1 \dots w_n$: words represented with vectors.
- Context vector for w: all words that co-occur with w.

The Vector Space Model of Word Meaning

• Similar words should have similar vectors.

Informatics 1 CG: Lecture 13

Constructing Vector Spaces Constructing Vector Spaces Words occur in context: Car engine hood tires truck trunk Car engine hood tires truck trunk Car engine hood tires truck trunk Car emissions hood make model trunk Car emissions hood make model trunk Chomsky corpus noun parsing tagging wonderful Chomsky corpus noun parsing tagging wonderful Contexts can be obtained from corpora (large collections of text). Chomsky corpus noun parsing tagging wonderful

Constructing Vector Spaces

Define the context (here: symmetric, -5, +5):

car engine hood tires truck trunk

car emissions hood make model trunk

Chomsky corpus noun parsing tagging wonderful

• Context words: engine, hood, tires, truck, trunk, car, emissions, make, model, corpus, noun, parsing, tagging, wonderful

The Vector Space Model of Word Meaning

• Dimensions of context vectors: 14

Informatics 1 CG: Lecture 13

Create co-occurrence matrix:

	car	corpus	emissions	engine	hood	make	model	unou	parsing	tagging	tires	truck	trunk	wonderful
car	0	0	0	1	1	0	0	0	0	0	1	1	1	0
hood	1	0	1	1	1	1	1	0	0	0	1	1	1	0
Chomsky	0	1	0	0	0	0	0	1	1	1	0	0	0	1

Constructing Vector Spaces

Informal algorithm for constructing vector spaces:

- pick the words you are interested in: target words;
- define number of words around target word: context window;
- count number of times the target word co-occurs with context words: co-occurrence matrix.

The context can also be defined in terms of documents, paragraphs, or sentences (rather than words around target word).

Constructing Vector Spaces

Measure the distance between vectors:

The cosine of the angle between two vectors \mathbf{x} and \mathbf{y} is:

$$cos(\mathbf{x}, \mathbf{y}) = \frac{\mathbf{x} \cdot \mathbf{y}}{||\mathbf{x}|| \cdot ||\mathbf{y}||} = \frac{\sum_{i=1}^{n} x_i y_i}{\sqrt{\sum_{i=1}^{n} x_i^2} \sqrt{\sum_{i=1}^{n} y_i^2}}$$

The Euclidean distance of two vectors **x** and **y** is:

$$||\mathbf{x} - \mathbf{y}|| = \sqrt{\sum_{i=1}^{n} (x_i - y_i)^2}$$

Many more similarity measures exist.

- We represent document semantics also using vectors.
- Bag-of-words (BOW) model: order of words is irrelevant.
- Nave version: represent documents by word counts.

	pet	bone	fur	run	brown	screen	mouse	fetch
d_1	0	2	0	3	5	0	0	1
d_2	1	0	1	0	8	0	0	0
<i>d</i> ₃	0	0	0	1	0	3	6	2

Document-term co-occurrence matrix

Using the Vector Space Model

documents and queries.

Can compute similarities between documents, or between

Query: "computer pointer"

Dimensionality Reduction

Informatics 1 CG: Lecture 13

Problem: the co-occurrence matrix can be very sparse (many zeros) and noisy (e.g., due to words with the same meaning).

auto engine bonnet tires lorry boot

car emissions hood make model trunk

make hidden Markov model emissions normalize

13

Dimensionality Reduction

Latent Semantic Analysis

In order to address these problems, reduce the dimensionality of the co-occurrence matrix M:

- project the word vectors into a different subspace so that vector cosines more accurately represent semantic similarity;
- in lower dimensional space, synonym vectors may not be orthogonal;
- singular value decomposition is a widely used projection method; many others exists.
- alternative: restrict matrix dimensions to most reliable words.

- Best known vector space model (Landauer and Dumais, 1997).
- Natural language engineering:
 - lexicon acquisition (e.g., synonyms), unsupervised morphology;
 - essay grading, text coherence;
 - information retrieval;
 - language modeling, summarization, etc.
- Cognitive science:
 - semantic priming;
 - TOEFL 2nd language learning test.

Semantic Priming

Till, Mross and Kintsch's (1988) lexical decision experiment

The gardener pulled the hose around to the holes in the yard. Perhaps the water would solve his problem with the **mole**.

ground face

ce drown cancer

The patient sensed that this was not a routine visit. The doctor hinted that there was reason to remove the **mole**.

ground face drown cancer

Simulating Semantic Priming

- Till, Mross and Kintsch's (1988) results:
 - words related to both senses of ambiguous word were primed immediately after presentation;
 - after about 300 ms only the context appropriate associates remained significantly primed;

LSA model predicts:

- Larger cosines between ambiguous word and its related words than its control word;
- Vector average of context has a higher cosine with semantically congruent words.

The TOEFL Task

Test of English as a Foreign Language tests non-native speakers' knowledge of English.

You will find the office at the main intersection.

- (a) place
- (b) crossroads
- (c) roundabout
- (d) building

This is a standard task in the cognitive modeling literature, and vectors space models are frequently used to solve it.

Informatics 1 CG: Lecture 13

The Vector Space Model of Word Meaning

The TOEFL Task

- 80 items: 1 word/4 alternative words.
- Compute semantic representations for probe and answer words
- Word with largest cosine to the probe is correct answer.
- LSA was trained on a 4.6 M corpus from encyclopedia.
- LSA answered 64.4% items correctly.
- Non-native speakers' average is 64.5%.
- This average is adequate for admission in many US universities.

Discussion

Strengths:

- fully automatic construction;
- representationally simple: all we need is a corpus and some notion of what counts as a word;
- language-independent, cognitively plausible.

Informatics 1 CG: Lecture 13

Weaknesses:

- many ad-hoc parameters when creating the model;
- ambiguous words: their meaning is the average of all senses;
- context words contribute indiscriminately to meaning.

The author received much acclaim for his new **book**. For author acclaim his much received new **book**.
