- 1 Morphology parsing: the problem
- 2 Finite-state transducers
- 3 FSTs for morphology parsing and generation

(This lecture is taken almost directly from Jurafsky & Martin chapter 3, sections 1–7.)

Morphological parsing: the problem

In many languages, words can be made up of a main **stem** (carrying the basic dictionary meaning) plus one or more **affixes** carrying grammatical information. E.g. in English:

Surface form:	cats	walking	smoothest
Lexical form:	cat+N+PL	walk+V+PresPart	smooth+Adj+Sup

Morphological parsing is the problem of extracting the lexical form from the surface form.

Should take account of:

- Irregular forms (e.g. goose → geese)
- Systematic rules (e.g. 'e' inserted before suffix 's' after s,x,z,ch,sh: fox → foxes, watch → watches)

Why bother?

- NLP tasks involving **meaning extraction** will often involve morphology parsing.
- Even a humble task like **spell checking** can benefit: e.g. is 'walking' a possible word form?

But why not just list all derived forms separately in our wordlist (e.g. walk, walks, walked, walking)?

- Might be OK for English, but not for a morphologically rich language — e.g. in Turkish, can pile up to 10 suffixes on a verb stem, leading to 40,000 possible forms for some verbs!
- Even for English, morphological parsing makes adding new words easier (e.g. 'frape').
- Morphology parsing is just **more interesting** than brute listing!

Parsing and generation

Parsing here means going from the surface to the lexical form.
E.g. foxes \rightarrow fox +N +PL.

Generation is the opposite process: fox +N +PL \rightarrow foxes. It's helpful to consider these two processes together.

Either way, it's often useful to proceed via an intermediate form, corresponding to an analysis in terms of **morphemes** (= minimal meaningful units) before **orthographic rules** are applied.

Surface form: foxes
Intermediate form: fox ^ s #
Lexical form: fox +N +PL

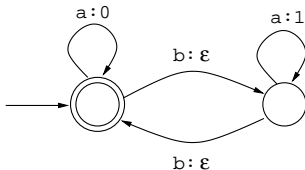

(^ means morpheme boundary, # means word boundary.)

N.B. The translation between surface and intermediate form is exactly the same if 'foxes' is a 3rd person singular verb!

Finite-state transducers

We can consider ϵ -NFAs (over an alphabet Σ) in which transitions may also (optionally) produce *output* symbols (over a possibly different alphabet Π).

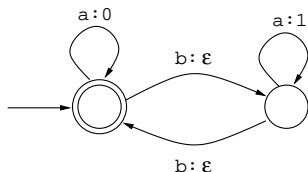

E.g. consider the following machine with input alphabet $\{a, b\}$ and output alphabet $\{0, 1\}$:

Such a thing is called a **finite state transducer**.

In effect, it specifies a (possibly multi-valued) translation from one regular language to another.

Clicker exercise

What output will this produce, given the input *abaaabbab*?

- 1 001110
- 2 001111
- 3 0011101
- 4 More than one output is possible.

Formal definition

Formally, a **finite state transducer** T with inputs from Σ and outputs from Π consists of:

- sets Q , S , F as in ordinary NFAs,
- a transition relation $\Delta \subseteq Q \times (\Sigma \cup \{\epsilon\}) \times (\Pi \cup \{\epsilon\}) \times Q$

From this, one can define a many-step transition relation $\hat{\Delta} \subseteq Q \times \Sigma^* \times \Pi^* \times Q$, where $(q, x, y, q') \in \hat{\Delta}$ means “starting from state q , the input string x can be translated into the output string y , ending up in state q' .” (Details omitted.)

Note that a finite state transducer can be run in either direction! From T as above, we can obtain another transducer \overline{T} just by swapping the roles of inputs and outputs.

Stage 1: From lexical to intermediate form

Consider the problem of translating a lexical form like 'fox+N+PL' into an intermediate form like 'fox ^ s #', taking account of irregular forms like goose/geese.

We can do this with a transducer of the following schematic form:

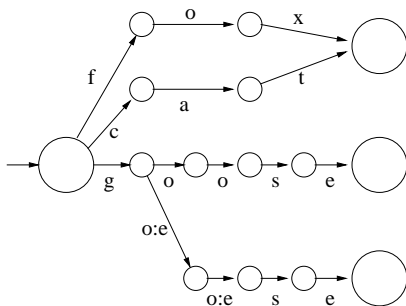

We treat each of +N, +SG, +PL as a single symbol.

The 'transition' labelled +PL : ^s# abbreviates three transitions:

+PL : ^, ε : s, ε : #.

The Stage 1 transducer fleshed out

The left hand part of the preceding diagram is an abbreviation for something like this (only a small sample shown):

Here, for simplicity, a single label u abbreviates $u : u$.

Stage 2: From intermediate to surface form

To convert a sequence of morphemes to surface form, we apply a number of **orthographic rules** such as the following.

- **E-insertion:** Insert e after s,z,x,ch,sh before a word-final morpheme -s. (fox → foxes)
- **E-deletion:** Delete e before a suffix beginning with e,i. (love → loving)
- **Consonant doubling:** Single consonants b,s,g,k,l,m,n,p,r,s,t,v are doubled before suffix -ed or -ing. (beg → begged)

We shall consider a simplified form of E-insertion, ignoring ch,sh.

(Note that this rule is oblivious to whether -s is a plural noun suffix or a 3rd person verb suffix.)

A transducer for E-insertion (adapted from J+M)

Here ? may stand for any symbol except $z,s,x,\hat{\cdot},\#$.

(Treat # as a 'visible space character'.)

At a morpheme boundary following z,s,x , we arrive in State 2.

If the ensuing input sequence is $s\#$, our only option is to go via states 3 and 4. **Note that there's no #-transition out of State 5.**

State 5 allows e.g. 'ex $\hat{\cdot}$ service $\hat{\cdot}$ men $\#$ ' to be translated to 'exservicemen'.

Putting it all together

FSTs can be **cascaded**: output from one can be input to another.

To go from lexical to surface form, use 'Stage 1' transducer followed by a bunch of orthographic rule transducers like the above.

The results of this **generation** process are typically **deterministic** (each lexical form gives a unique surface form), even though our transducers make use of non-determinism along the way.

Running the same cascade **backwards** lets us do **parsing** (surface to lexical form). Because of ambiguity, this process is frequently **non-deterministic**: e.g. 'foxes' might be analysed as fox+N+PL or fox+V+Pres+3SG.

Such ambiguities are not resolved by morphological parsing itself: left to a later processing stage.

Clicker exercise 2

Apply this **backwards** to translate from surface to int. form.

Starting from state 0, how many **sequences of transitions** are compatible with the input string 'asses' ?

- ① 1
- ② 2
- ③ 3
- ④ 4
- ⑤ More than 4

Solution

On the input string 'asses', 10 transition sequences are possible!

- $0 \xrightarrow{a} 0' \xrightarrow{s} 1 \xrightarrow{s} 1 \xrightarrow{\epsilon} 2 \xrightarrow{e} 3 \xrightarrow{s} 4$, output $ass\hat{s}$
- $0 \xrightarrow{a} 0' \xrightarrow{s} 1 \xrightarrow{s} 1 \xrightarrow{\epsilon} 2 \xrightarrow{e} 0' \xrightarrow{s} 1$, output $ass\hat{e}s$
- $0 \xrightarrow{a} 0' \xrightarrow{s} 1 \xrightarrow{s} 1 \xrightarrow{e} 0' \xrightarrow{s} 1$, output $asses$
- $0 \xrightarrow{a} 0' \xrightarrow{s} 1 \xrightarrow{\epsilon} 2 \xrightarrow{s} 5 \xrightarrow{\epsilon} 2 \xrightarrow{e} 3 \xrightarrow{s} 4$, output $as\hat{s}\hat{s}$
- $0 \xrightarrow{a} 0' \xrightarrow{s} 1 \xrightarrow{\epsilon} 2 \xrightarrow{s} 5 \xrightarrow{\epsilon} 2 \xrightarrow{e} 0' \xrightarrow{s} 1$, output $as\hat{s}\hat{e}s$
- $0 \xrightarrow{a} 0' \xrightarrow{s} 1 \xrightarrow{\epsilon} 2 \xrightarrow{s} 5 \xrightarrow{e} 0' \xrightarrow{s} 1$, output $as\hat{s}es$
- Four of these can also be followed by $1 \xrightarrow{\epsilon} 2$ (output $\hat{\quad}$).
