LL(1) grammars and parse tables
Predictive parsing using a parse table
When is a grammar LL(1)?

13 October 2016
A pushdown automaton (PDA) uses control states and a stack to recognise input strings.

We considered PDAs whose goal is to empty the stack after having read the input string.

The languages recognised by nondeterministic pushdown automata (NPDAs) are exactly the context-free languages.

Different to the situation for finite automata, deterministic pushdown automata (DPDAs) are less powerful than NPDAs. (The definition of DPDAs is subtle and beyond the scope of Inf2A, though related material will be covered in Tutorial 3.)
Predictive parsing: first steps

Consider how we would like to parse a program in the little programming language from Lecture 9.

stmt → if-stmt | while-stmt | begin-stmt | assg-stmt
if-stmt → if bool-expr then stmt else stmt
while-stmt → while bool-expr do stmt
begin-stmt → begin stmt-list end
stmt-list → stmt | stmt ; stmt-list
assg-stmt → VAR := arith-expr
bool-expr → arith-expr compare-op arith-expr
compare-op → < | > | <= | >= | == | !=

We read the lexed program token-by-token from the start.
The start symbol of the grammar is `stmt`.

Suppose the first lexical class in the program is `begin`.

From this information, we can tell that the first production in the syntax tree must be

```
stmt → begin-stmt
```

We thus have to parse the program as `begin-stmt`.

We now see that the next production in the syntax tree has to be

```
begin-stmt → begin stmt-list end
```

We thus have to parse the full program `begin .......` as `begin stmt-list end`.

We can thus step over `begin`, and proceed to parse the remaining program `.......` as `stmt-list end`, etc.
In the example, the correct production to apply is being determined from just two pieces of information:

- current lexical class
- a predicted nonterminal symbol.

If it is always possible to determine the next production from the above information, the grammar is said to be **LL(1)**.

When a grammar is **LL(1)**, parsing can run **efficiently** and **deterministically**.

As it turns out, in spite of the promising start to parsing on the previous slides, the grammar for our little programming language is **not** **LL(1)**. However, we shall see in Lecture 14 how the grammar can be **repaired** to provide an **LL(1)** grammar for the same language.
LL(1) grammars: another intuition

Think about a (one-state) NPDA derived from a CFG \( \mathcal{G} \).

At each step, our NPDA can ‘see’ two things:

- the current input symbol
- the topmost stack symbol

Roughly speaking, \( \mathcal{G} \) is an **LL(1) grammar** if, just from this information, it’s possible to determine which transition/production to apply next.

Here LL(1) means ‘read input from **Left**, build **Leftmost** derivation, look just **one** symbol ahead’.

**Subtle point:** When doing LL(1) parsing (as opposed to executing an NPDA) we use the input symbol to help us choose a production without consuming the input symbol . . . hence **look ahead**.
Parse tables

Saying the current input symbol and stack symbol uniquely determine the production means we can draw up a two-dimensional parse table telling us which production to apply in any situation.

Consider e.g. the following grammar for well-bracketed sequences:

\[
S \rightarrow \epsilon \mid TS \\
T \rightarrow (S)
\]

This has the following parse table:

<table>
<thead>
<tr>
<th></th>
<th>(</th>
<th>$</th>
</tr>
</thead>
<tbody>
<tr>
<td>(S)</td>
<td>(S \rightarrow TS)</td>
<td>(S \rightarrow \epsilon) (S \rightarrow \epsilon)</td>
</tr>
<tr>
<td>(T)</td>
<td>(T \rightarrow (S))</td>
<td></td>
</tr>
</tbody>
</table>

- **Columns** are labelled by **terminals**, which are the input symbols. We include an extra column for an ‘end-of-input’ marker $\$.  
- **Rows** are labelled by **nonterminals**.  
- **Blank entries** correspond to situations that can never arise in processing a legal input string.
Predictive parsing with parse tables

Given such a parse table, parsing can be done very efficiently using a stack. The stack (reading downwards) records the predicted sentential form for the remaining part of the input.

- Begin with just start symbol $S$ on the stack.
- If current input symbol is $a$ (maybe $\epsilon$), and current stack symbol is a non-terminal $X$, look up rule for $a, X$ in table. [Error if no rule.] If rule is $X \rightarrow \beta$, pop $X$ and replace with $\beta$ (pushed right-end-first!)
- If current input symbol is $a$ and stack symbol is $a$, just pop $a$ from stack and advance input read position. [Error if stack symbol is any other terminal.]
- Accept if stack empties with $\epsilon$ as input symbol. [Error if stack empties sooner.]
Example of predictive parsing

Let's use this table to parse the input string `(()).`

<table>
<thead>
<tr>
<th>Operation</th>
<th>Remaining input</th>
<th>Stack state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lookup <code>(</code>, <code>S</code></td>
<td><code>()</code>$</td>
<td><code>S</code></td>
</tr>
<tr>
<td>Lookup <code>(</code>, <code>T</code></td>
<td><code>()</code>$</td>
<td><code>TS</code></td>
</tr>
<tr>
<td>Match <code>(</code></td>
<td><code>()</code>$</td>
<td><code>(S)</code></td>
</tr>
<tr>
<td>Lookup <code>(</code>, <code>S</code></td>
<td><code>()</code>$</td>
<td><code>(S)</code></td>
</tr>
<tr>
<td>Match <code>(</code></td>
<td><code>)</code>$</td>
<td><code>(S)</code></td>
</tr>
<tr>
<td>Lookup <code>)</code>, <code>S</code></td>
<td><code>)</code>$</td>
<td><code>)</code></td>
</tr>
<tr>
<td>Match <code>)</code></td>
<td><code>)</code>$</td>
<td><code>S</code></td>
</tr>
<tr>
<td>Lookup <code>)</code>, <code>S</code></td>
<td><code>)</code>$</td>
<td><code>)</code></td>
</tr>
<tr>
<td>Match <code>)</code></td>
<td><code>$</code></td>
<td><code>S</code></td>
</tr>
<tr>
<td>Lookup <code>$</code>, <code>S</code></td>
<td><code>$</code></td>
<td>empty stack</td>
</tr>
</tbody>
</table>

(Also easy to build a syntax tree as we go along!)
For each of the following two input strings:

For ), we start by expanding $S$ to $\epsilon$. But this empties the stack, whereas we haven’t consumed any input yet.

For (, we get to a point where we’ve reached the end marker $\$ in the input, which doesn’t match the predicted symbol ‘)’ on the stack.

1. Blank entry in table encountered
2. Input symbol (or end marker) doesn’t match expected symbol
3. Stack empties before end of string reached
Self-assessment questions

\[
\begin{array}{ccc}
S & ( & $ \\
S \rightarrow TS & S \rightarrow \epsilon & S \rightarrow \epsilon \\
T & T \rightarrow (S) & \\
\end{array}
\]

For each of the following two input strings:

\[
( )
\]

what will go wrong when we try to apply our parsing algorithm?

1. Blank entry in table encountered
2. Input symbol (or end marker) doesn’t match expected symbol
3. Stack empties before end of string reached

**Answer:** For ), we start by expanding $S$ to $\epsilon$. But this empties the stack, whereas we haven’t consumed any input yet.

For (, we get to a point where we’ve reached the end marker $\$$ in the input, which doesn’t match the predicted symbol ‘)’ on the stack.
Further remarks

**Slogan:** the parse table entry for $a, X$ tells us which rule to apply if we’re expecting an $X$ and see an $a$.

- Often, the $a$ will be simply the *first* symbol of the $X$-subphrase in question.
- But not always: maybe the $X$-subphrase in question is $\epsilon$, and the $a$ belongs to whatever follows the $X$.

E.g. in the lookups for $)$, $S$ on the previous slide, the $S$ in question turns out to be empty.

Once we’ve got a parse table for a given grammar $G$, we can parse strings of length $n$ in $O(n)$ time (and $O(n)$ space).

Our algorithm is an example of a **top-down predictive parser**: it works by ‘predicting’ the form of the remainder of the input, and builds syntax trees a top-down way (i.e. starting from the root). There are other parsers (e.g. LR(1)) that work ‘bottom up’. 
LL(1) grammars: formal definition

Suppose $G$ is a CFG containing no ‘useless’ nonterminals, i.e.

- every nonterminal appears in some sentential form derived from the start symbol;
- every nonterminal can be expanded to some (possibly empty) string of terminals.

We say $G$ is LL(1) if for each terminal $a$ and nonterminal $X$, there is some production $X \rightarrow \alpha$ with the following property:

If $b_1 \ldots b_nX\gamma$ is a sentential form appearing in a leftmost derivation of some string $b_1 \ldots b_nac_1 \ldots c_m$ ($n, m \geq 0$), the next sentential form appearing in the derivation is necessarily $b_1 \ldots b_n\alpha\gamma$.

(Note that if $a, X$ corresponds to a ‘blank entry’ in the table, any production $X \rightarrow \alpha$ will satisfy this property, because a sentential form $b_1 \ldots b_nX\gamma$ can’t arise.)
Non-LL(1) grammars

Roughly speaking, a grammar is **by definition** LL(1) if and only if there’s a parse table for it. Not all CFGs have this property!

Consider e.g. a different grammar for the same language of well-bracketed sequences:

\[ S \rightarrow \epsilon \mid (S) \mid SS \]

Suppose we’d set up our initial stack with S, and we see the input symbol (. What rule should we apply?

- If the input string is (()), should apply \( S \rightarrow (S) \).
- If the input string is ()(), should apply \( S \rightarrow SS \). We can’t tell without looking further ahead.

**Put another way:** if we tried to build a parse table for this grammar, the two rules \( S \rightarrow (S) \) and \( S \rightarrow SS \) would be competing for the slot (, S. So this grammar is **not** LL(1).
Easy to see from the definition that any LL(1) grammar will be **unambiguous**: never have two syntax trees for the same string.

- For **computer languages**, this is fine: normally want to avoid ambiguity anyway.
- For **natural languages**, ambiguity is a fact of life! So LL(1) grammars are normally inappropriate.

Two outstanding questions...

- How can we tell if a grammar is LL(1) — and if it is, how can we construct a parse table? (See Lecture 12.)
- If a grammar isn’t LL(1), is there any hope of replacing it by an equivalent one that is? (See Lecture 14.)
Relevant reading:

- Some lecture notes from a previous year (covering the same material but with different examples) are available via the course website. (See Readings column of course schedule.)
