э

PROBLEM: Guiding a robot to a target based on images APPLICATIONS:

- Assembly robotics: Component insertion
- Mobile robotics: Docking

\implies VISUAL SERVOING THEORY

<個> < 回> < 回> < 回> = 回

If only vertical robot motion possible (and sufficient) to reduce the gap:

• Imp • • model

3. 3

How to get peg exactly into hole?

APPROACH 1: MODEL DRIVEN

KNOWN:

- Robot manipulation model
- Part & robot position known
- Target model
- Camera calibrated

BUT: errors exist and combine - noise, unknowns, gear backlash

<個> < 回> < 回> → 回

SO: need very accurate calibration & mechanisms

TRY 2: VISUAL SERVOING

Move so that observed positions directly link to task distances

- Incrementally move to reduce image gap
- Don't know exact positions

MORE FORMAL MODEL

CONSIDER:

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

э

- **B** ROBOT POSITION WRT SCENE
- C CAMERA POSITION WRT SCENE
- P CAMERA PROJECTION MODEL
- $\vec{\theta}$ ROBOT JOINT PARAMETERS $R\left(\vec{\theta}\right)$ TOOL POSITION WRT ROBOT

▲圖 ▶ ▲ 臣 ▶ ▲ 臣 ▶

э

IF:

- \vec{x} TOOL TIP WRT TOOL
- \vec{z} TARGET WRT SCENE
- a IMAGE OF TOOL TIP
- \vec{b} IMAGE OF TARGET

THEN (as a concatenation of appropriate transformations):

▲□ ▶ ▲ □ ▶ ▲ □ ▶

3

•
$$\vec{a} = PC^{-1}BR(\theta)\vec{x}$$

•
$$\vec{b} = PC^{-1}\vec{z}$$

Calibrate *P*, *C*, *B*,
$$R(\vec{\theta})$$
 accurately
SOLVE: $\vec{\theta} = \vec{f}(\vec{z}, \vec{x}, P, C, B)$

Hard analytics

Not always solvable

How much to move joints $(\Delta \vec{\theta})$ to reduce target error $\vec{\Delta} = \vec{a} - \vec{b}$? Visually estimate $\vec{f}(\cdots)$ such that $\Delta \vec{\theta} \doteq \vec{f}(\vec{\Delta})$ Use $\Delta \vec{\theta}$ to partially approach target and recompute $\vec{\theta}$ Iterate

(日本)(日本)(日本)(日本)

ESTIMATING $\vec{f}()$

Move robot joint *i* slightly from θ_i to $\theta_i + \varepsilon$ Observe tool tip moves slightly from \vec{a} to $\vec{a} + \vec{\delta}_i$ Compute:

$$\frac{\partial \vec{a}}{\partial \theta_i} \doteq \frac{\left(\vec{a} + \vec{\delta}_i\right) - \vec{a}}{\left(\theta_i + \varepsilon\right) - \theta_i} = \frac{\vec{\delta}_i}{\varepsilon}$$

Repeat for all *i* to estimate JACOBIAN matrix

$$J = \frac{1}{\varepsilon} \left[\vec{\delta}_1, \ldots, \vec{\delta}_N \right]$$

<個> < 回> < 回> → 回

for N joints.

Linear theory:

$$ec{\Delta} \doteq J \Delta ec{ heta}$$

J is $2 \times N$, so use pseudo-inverse

$$\Delta ec{ heta} = \left(J^ op J
ight)^{-1} J^ op ec{\Delta}$$

<個> < 回> < 回> → 回

But J is only approximate and not true inverse? So, move $\alpha \Delta \vec{\theta}$ and iterate ($\alpha < 1$)

SERVOING ALGORITHM

see Perceptual Actions: Vision Based Uncalibrated Robot Control by Martin Jägersand

イロト イポト イヨト イヨト 三日

DO

Compute $\vec{\Delta}$ Estimate JCompute $\Delta \vec{\theta}$ Move joints $\alpha \Delta \vec{\theta}$ where $0 < \alpha < 1$ WHILE $\|\vec{\Delta}\| > \tau$ pixels

・得い くまい くまい

э

au > 1? Maybe robot is 'shakey'

If α small enough, should always be reducing Δ As J is linear, moving $\alpha \Delta \vec{\theta}$ should reduce position error by approximately $\alpha \vec{\Delta}$

▲□ ▶ ▲ □ ▶ ▲ □ ▶

э

CONVERGENCE

STEP	MOVEMENT	REMAINDER
1	$\alpha \ \vec{\Delta} \ $	$(1-lpha) \ ec{\Delta}\ $
2	$(1 - lpha) lpha \ ec{\Delta} \ $	$(1-lpha)^2 \ ec{\Delta}\ $
	• • •	
n	$(1-\alpha)^{n-1} \alpha \ \vec{\Delta}\ $	$(1-lpha)^n \ ec{\Delta}\ $

Total movement:

$$\sum_{n=1}^{\infty} (1-\alpha)^{n-1} \alpha \|\vec{\Delta}\| = \frac{1}{1-(1-\alpha)} \alpha \|\vec{\Delta}\| = \|\vec{\Delta}\|$$

э

5 iterations

- Usually more cameras (image-based visual servoing)
- If the pose of the robot can be estimated based on a robot model a single camera may be sufficient (position-based visual servoing)
- Precision is improved by combination with force feedback
- Camera movements and other sources of errors
- Related problem: Camera positioning; track following in autonomous robots
