# Dish Stacking with Reinforcement Learning

## Solution Sheet

1.

- $a_0 = Grab$   $s_0 = No Plate Held$
- a<sub>1</sub> = Dry s<sub>1</sub> = Wet Plate Held
- a<sub>2</sub> = Store s<sub>2</sub> = Dry Plate Held

s<sub>3</sub> = Finished

## **Reward Function**

	a <sub>0</sub>	a1	a <sub>2</sub>
S <sub>0</sub>	0	0	0
S1	-20	$P_{f}(-20) + \sim p_{f}(0) = -2$	5
\$2	-20	$P_{f}(-20) + \sim p_{f}(0) = -2$	10
S <sub>3</sub>	0	0	0

#### **Transition Function**

a <sub>0</sub>	S <sub>0</sub>	\$ <sub>1</sub>	\$ <sub>2</sub>	\$ <sub>3</sub>
S <sub>0</sub>	0	1	0	0
S1	0	1	0	0
\$2	0	1	0	0
S <sub>3</sub>	0	0	0	1

a <sub>1</sub>	S <sub>0</sub>	S <sub>1</sub>	S <sub>2</sub>	S <sub>3</sub>
So	1	0	0	0
S <sub>1</sub>	0	P <sub>f</sub> = 0.1	~p <sub>f</sub> = 0.9	0
\$2	0	P <sub>f</sub> = 0.1	~p <sub>f</sub> = 0.9	0
S <sub>3</sub>	0	0	0	1

a <sub>2</sub>	S <sub>0</sub>	S <sub>1</sub>	\$ <sub>2</sub>	S <sub>3</sub>
S <sub>0</sub>	0	0	0	1
S1	0	0	0	1
\$2	0	0	0	1
S <sub>3</sub>	0	0	0	1

2. A)Example Solution: This MDP is episodic and has a terminating state "finished". Therefore we can set  $\gamma$ =1.

Set a deterministic policy, I chose to always grab. As finished is the terminal state its action does not matter.

Policy

S <sub>0</sub>	a <sub>0</sub>
S <sub>1</sub>	a <sub>0</sub>
\$2	a <sub>0</sub>

First I do a policy Evaluation to find  $V^{\text{policy}}$ 

S <sub>0</sub>	0
S1	-20
\$ <sub>2</sub>	-20

Now for a policy improvement step. First I need to determine Q(s,a)

	a <sub>0</sub>	-20		$a_0$	-20		a <sub>0</sub>	-20
S <sub>0</sub>	a1	0	<b>S</b> 1	a1	P <sub>f</sub> (-20) + ~p <sub>f</sub> (-20) = -2 -18 = -20	S <sub>2</sub>	a1	P <sub>f</sub> (-20) + ~p <sub>f</sub> (-20) = -2 -18 = -20
	a₂	0		a <sub>2</sub>	5		a <sub>2</sub>	10

I now set the policy to greedily choose the highest value action (random if there's a tie)

Policy

S <sub>0</sub>	a1
\$ <sub>1</sub>	a <sub>2</sub>
\$ <sub>2</sub>	a2

The policy has changes so I must do the loop again. Policy evaluation 2:

Vpolicy

S <sub>0</sub>	0
S <sub>1</sub>	5
\$2	10

Policy Improvement 2:

Q(s,a)

	a <sub>0</sub>	5		$a_0$	-20		a <sub>0</sub>	-20
<b>S</b> 0	a1	0	<b>S</b> 1	a1	$P_{f}(-20) + \sim p_{f}(10) =$ -2 + 9 = 7	S <sub>2</sub>	a1	$P_{f}(-20) + \sim p_{f}(10) =$ -2 + 9 = 7
	$a_2$	0		a <sub>2</sub>	5		a <sub>2</sub>	10

Policy

S <sub>0</sub>	a <sub>0</sub>
S <sub>1</sub>	a1
\$2	a <sub>2</sub>

Policy Evaluation 2:

V<sup>policy</sup>

S <sub>0</sub>	5
S1	7
\$ <sub>2</sub>	10

Policy Improvement 2:

Q(s,a)

	a <sub>0</sub>	7		a <sub>0</sub>	-20		a <sub>0</sub>	-20
S <sub>0</sub>	a1	0	$S_1$	a1	$P_{f}(-20) + ^{p_{f}}(10) =$ -2 + 9 = 7	S <sub>2</sub>	$a_1$	$P_{f}(-20) + \sim p_{f}(10) =$ -2 + 9 = 7
	a <sub>2</sub>	0		a <sub>2</sub>	5		a <sub>2</sub>	10

Policy

S <sub>0</sub>	a <sub>0</sub>		
S <sub>1</sub>	<b>a</b> 1		
\$2	a <sub>2</sub>		

The policy didn't change so the algorithm is complete.

2B) To do a value iteration, I don't choose an original policy and set the initial values to the highest possible reward from possible actions

Value

S <sub>0</sub>	0
\$ <sub>1</sub>	5
\$ <sub>2</sub>	10

Recalculate Q

		a <sub>0</sub>	5		a <sub>0</sub>	-20	]		a <sub>0</sub>	-20
9	<b>S</b> 0	a1	0	<b>S</b> 1	a1	P <sub>f</sub> (-20) + ∼p <sub>f</sub> (10) = -2 + 9 = 7		S <sub>2</sub>	$a_1$	$P_{f}(-20) + \sim p_{f}(10) =$ -2 + 9 = 7
		a <sub>2</sub>	0		a <sub>2</sub>	5			a <sub>2</sub>	10

Recalculate V

S <sub>0</sub>	5
S <sub>1</sub>	7
\$2	10

## Recalculate Q

	$a_0$	7		$a_0$	-20		a <sub>0</sub>	-20
<b>S</b> 0	a1	0	<b>S</b> 1	aı	P <sub>f</sub> (-20) + ∼p <sub>f</sub> (10) = -2 + 9 = 7	S <sub>2</sub>	a1	$P_{f}(-20) + \sim p_{f}(10) =$ -2 + 9 = 7
	$a_2$	0		a <sub>2</sub>	5		a <sub>2</sub>	10

Recalculate V

S <sub>0</sub>	7		
S <sub>1</sub>	7		
\$ <sub>2</sub>	10		

## Recalculate Q

	a <sub>0</sub>	7		$a_0$	-20		a <sub>0</sub>	-20
S <sub>0</sub>	a1	0	<b>S</b> 1	a1	$P_{f}(-20) + \sim p_{f}(10) =$ -2 + 9 = 7	S <sub>2</sub>	a1	$P_{f}(-20) + \sim p_{f}(10) =$ -2 + 9 = 7
	a₂	0		a <sub>2</sub>	5		a <sub>2</sub>	10

Recalculate V

S <sub>0</sub>	7
S1	7
S <sub>2</sub>	10

It hasn't changed so the iteration is complete and now we choose the policy based on the maximum Q values

Policy

S <sub>0</sub>	a <sub>0</sub>		
\$1	a <sub>1</sub>		
\$2	a <sub>2</sub>		

2C) I will use  $\varepsilon$ -greedy exploration, so a policy will not always choose the maximum Q. I also need to define a limit to the number actions before the episode terminates, I'll choose 3. I will set  $\gamma$ =1.

First-visit MC (I only consider the reward of the first time I explore a state-action pair each episode):

1<sup>st</sup> "random" policy.

S <sub>0</sub>	a <sub>1</sub>
\$ <sub>1</sub>	a <sub>2</sub>
\$ <sub>2</sub>	a <sub>1</sub>

1<sup>st</sup> Episode (random start)

 $s_2 - (0) \rightarrow s_2 - (-20) \rightarrow s_1 - (0) \rightarrow s_1$ 

#### Estimate Q

	a <sub>0</sub>	0
<b>S</b> 0	a1	0
	a <sub>2</sub>	0

S1 a1 0   a2 0 0		a <sub>0</sub>	0
a <sub>2</sub> 0	$S_1$	a1	0
		a <sub>2</sub>	0

	a <sub>0</sub>	0
<b>S</b> <sub>2</sub>	$a_1$	0
	a2	0

2<sup>nd</sup> policy chosen based on Q with some error.

S <sub>0</sub>	a <sub>0</sub>
\$1	a <sub>2</sub>
S <sub>2</sub>	a <sub>0</sub>

## 2<sup>nd</sup> Episode

s<sub>1</sub>-(5)-> s<sub>3</sub>

## Estimate Q

	a <sub>0</sub>	0
S <sub>0</sub>	a1	0
	a <sub>2</sub>	0

	$a_0$	0
$S_1$	a1	0
	a <sub>2</sub>	5

	$a_0$	0
<b>S</b> <sub>2</sub>	a1	0
	a <sub>2</sub>	0

# 3<sup>rd</sup> Policy.

S <sub>0</sub>	a <sub>0</sub>
S <sub>1</sub>	a <sub>2</sub>
S <sub>2</sub>	a1

# 3<sup>rd</sup> Episode

# Estimate Q

		a <sub>0</sub>	0.5*5 = 2.5						
	_	<b>u</b> 0	0.5 5 - 2.5		$a_0$	0		a <sub>0</sub>	0
S	5 L	a1	0	<b>S</b> 1	a1	0	<b>S</b> <sub>2</sub>	a1	0
		a <sub>2</sub>	0		a <sub>2</sub>	5		a <sub>2</sub>	0

Etc...

2D) Every-visit MC (I average the rewards that I receive from multiple explorations of a state-action pair each episode):

1<sup>st</sup> "random" policy.

S <sub>0</sub>	a1
\$ <sub>1</sub>	a <sub>2</sub>
S <sub>2</sub>	a1

1<sup>st</sup> Episode (random start)

 $s_2 - (0) -> s_2 - (-20) -> s_1 - (0) -> s_1$ 

## Estimate Q

<b>S</b> 0	a <sub>0</sub>	0
	a1	0
	a <sub>2</sub>	0

	a <sub>0</sub>	0			a <sub>0</sub>	0
$S_1$	a1	0		S <sub>2</sub>	$a_1$	(0-20)/2 = -10
	a <sub>2</sub>	0			a <sub>2</sub>	0
			1		- 4	-

2<sup>nd</sup> policy chosen based on Q with some error.

S <sub>0</sub>	ao
S1	a <sub>2</sub>
\$ <sub>2</sub>	a1

# 2<sup>nd</sup> Episode

s₁ –(5)-> s₃

## Estimate Q

S <sub>0</sub>	$a_0$	0			a <sub>0</sub>	0	]		$a_0$	0
	2.	0	-	$S_1$	a1	0		<b>S</b> <sub>2</sub>	$a_1$	-10
	a1	0		a <sub>2</sub>	5			a <sub>2</sub>	0	
	$a_2$	0								

# 3<sup>rd</sup> Policy.

S <sub>0</sub>	a <sub>0</sub>
S <sub>1</sub>	a <sub>2</sub>
\$ <sub>2</sub>	a1

3<sup>rd</sup> Episode

 $s_0 - (0) -> s_1 - (5) -> s_3$ 

# Estimate Q

	a <sub>0</sub>	0.5*5 = 2.5	1						
	<b>u</b> <sub>0</sub>	0.5 5 - 2.5			$a_0$	0		ao	0
So	a1	0		<b>S</b> 1	a1	0	<b>S</b> <sub>2</sub>	a1	-10
	a <sub>2</sub>	0			a <sub>2</sub>	5		a <sub>2</sub>	0
									•

Etc...

2E) I will use the same set up as in Monte Carlo but without a maximum length for each episode and with  $\alpha$ =0.7.

Update Q values after each step and choose action based on Q each step (with error). For SARSA the update to a Q value uses the formula:

 $Q(s,a) = Q(s,a) + \alpha(r + \gamma Q(s',a') - Q(s,a))$ 

Where s' is the next state and a' is the action you will take in that state based on your policy.

Start episode at s<sub>2</sub>

s<sub>2</sub>-(10)-> s<sub>3</sub>

Update Q(s<sub>2</sub>, a<sub>2</sub>)

	a <sub>0</sub>	0
S <sub>2</sub>	a1	0
	a <sub>2</sub>	O+0.7(10+ (0.5*0)-0) = 7

Start new episode at s<sub>1</sub>

s<sub>1</sub>-(0)-> s<sub>2</sub>

 $a_2$  selected as a'. Update Q( $s_1$ ,  $a_1$ ) using value for Q( $s_2$ ,  $a_2$ )

	a <sub>0</sub>	0
<b>S</b> 1	a1	0 + 0.7(0+ (0.5*7)-0) = 2.45
	a <sub>2</sub>	0

s<sub>2</sub>-(10)-> s<sub>3</sub>

Update Q(s<sub>2</sub>, a<sub>2</sub>)

	a <sub>0</sub>	0
S <sub>2</sub>	a1	0
	a <sub>2</sub>	7+0.7(10+ (0.5*0)-7) = 9.1

Start new episode at s2

At this point the  $\epsilon$ -greedy algorithm chooses  $a_1$  for a' rather than the action with maximum Q. The plate then breaks while trying to dry it.

s<sub>2</sub>-(-20)-> s<sub>1</sub>

At this point the  $\varepsilon$ -greedy algorithm chooses  $a_2$  for a' rather than the action with maximum Q.

Update  $Q(s_2, a_1)$  using value for  $Q(s_1, a_2)$ 

	a <sub>0</sub>	0
S <sub>2</sub>	a1	0 + 0.7(-20+(0.5*0)-0) = -15
	a <sub>2</sub>	9.1

2F) I will use the same set up as in Monte Carlo but without a maximum length for each episode and with  $\alpha$ =0.7.

For Q-Learning the update to Q(s,a) uses the formula:

 $Q(s,a) = Q(s,a) + \alpha(r + \gamma \max_{a'}Q(s',a') - Q(s,a))$ 

Where s' is the next state and a' is chosen to maximise Q(s',a').

Start episode at s<sub>2</sub>

s<sub>2</sub>-(10)-> s<sub>3</sub>

Update Q(s<sub>2</sub>, a<sub>2</sub>)

	a <sub>0</sub>	0
S <sub>2</sub>	a1	0
	a <sub>2</sub>	O+0.7(10+ (0.5*0)-0) = 7

Start new episode at s1

s<sub>1</sub>-(0)-> s<sub>2</sub>

 $a_2$  selected as a'. Update Q(s<sub>1</sub>,  $a_1$ ) using value for Q(s<sub>2</sub>,  $a_2$ ) as this is max<sub>a'</sub>Q(s', a').

	a <sub>0</sub>	0
<b>S</b> <sub>1</sub>	a1	0 + 0.7(0+ (0.5*7)-0) = 2.45
	a <sub>2</sub>	0

s<sub>2</sub>-(10)-> s<sub>3</sub>

Update Q(s<sub>2</sub>, a<sub>2</sub>)

	a <sub>0</sub>	0
S <sub>2</sub>	a1	0
	a <sub>2</sub>	7+0.7(10+ (0.5*0)-7) = 9.1

Start new episode at s2

At this point the  $\varepsilon$ -greedy algorithm chooses  $a_1$  for a' rather than the action with maximum Q. The plate then breaks while trying to dry it.

s<sub>2</sub>-(-20)-> s<sub>1</sub>

At this point the  $\varepsilon$ -greedy algorithm chooses  $a_2$  for a' rather than the action with maximum Q.

Update  $Q(s_2, a_1)$  using value for  $\underline{Q(s_1, a_1)}$  as this is  $\max_{a'}Q(s', a')$ .

	$a_0$	0
S <sub>2</sub>	a1	0 + 0.7(-20+(0.5*2.45)-0) = -13.14
	a <sub>2</sub>	9.1

5. You need to use Monte Carlo or Temporal Difference Learning as the others rely on a complete model.

6. Increasing the  $\varepsilon$  value in an  $\varepsilon$ -greedy algorithm causes it to become more explorative rather than exploitative. This means the learning algorithm will examine more possible actions and state pairs while looking for an optimal policy. Setting this value too small can hinder finding the optimal policy as the algorithm may not explore enough and never find it. On the other hand, a higher  $\varepsilon$  value can also increase the time taken to find an optimal policy due to the increased time exploring the rest of the state space.
