

# Spectral Graph theory

Rik Sarkar

# Course

- No class on Friday 23rd.
- Piazza forum to discuss projects, exercises, topics...
  - <https://piazza.com/ed.ac.uk/fall2015/infr11124>
- Deadline for project selection?

- Preliminary plan deadline: approx Nov 5 (not graded)
- Preliminary plan/proposal (short document)
  - Make sure you understand the problem
  - Have the data
  - Have a plan of approach

# Spectral methods

- Understanding a graph using eigen values and eigen vectors of the matrix
- We saw:
- Ranks of web pages: components of 1st eigen vector of suitable matrix
- Pagerank or HITS are algorithms designed to compute the eigen vector
- Today: other ways spectral methods help in network analysis

# Laplacian

- $L = D - A$

$$\begin{bmatrix} 1 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} - \begin{bmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$

- An eigen vector has one value for each node
- We are interested in properties of these values

# Application 1: Drawing a graph

- Problem: Computer does not know what a graph is supposed to look like
- A graph is a jumble of edges
- Consider a grid graph:
- We want it drawn *nicely*

# Graph embedding

- Find positions for vertices of a graph in low dimension (compared to  $n$ )
  - One eigen vector gives  $x$  values of nodes
  - Other gives  $y$ -values of nodes ... etc
- Preserves some properties of the graph e.g. approximate distances between vertices
  - Useful in visualization
  - Finding approximate distances

# Intuitions: the 1-D case

- Suppose we take the  $j$ th eigen vector of a chain
- What would that look like?
- We are going to plot the chain along  $x$ -axis
- The  $y$  axis will have the value of the node in the  $j$ th eigen vector
- We want to see how these rise and fall

# Observations

- $j = 0$
- $j = 1$
- $j = 2$
- $j = 3$
- $j = 19$

For All  $j$

# Observations

- In Dim 1 grid:
  - $v[1]$  is monotone
  - $v[2]$  is not monotone
- In dim 2 grid:
  - both  $v[1]$  and  $v[2]$  are monotone in suitable directions
- For low values of  $j$ :
  - Nearby nodes have similar values
    - Useful for embedding

# Application 2: Coloring

- Coloring: Assign colors to vertices, such that neighboring vertices do not have same color
  - E.g. Assignment of radio channels to wireless nodes. Good coloring reduces interference
- Idea: High eigen vectors give *dissimilar* values to nearby nodes
  - Use for coloring!

# Application 3: Cuts/ segmentation/clustering

- Find the smallest 'cut'
- A small set of edges whose removal disconnects the graph
- Clustering, community detection...

# Clustering/community detection

- $v[1]$  tends to stretch the narrow connections: discriminates different communities

# Clustering: community detection

- More communities
- Need higher dimensions
- Warning: it does not always work so cleanly
- In this case, the data is very symmetric

# Image segmentation

Shi & malik '00

$v[1]$

$$weight(i, j) \approx e^{-(px_i - px_j)^2}$$

# Laplacian matrix

- Imagine a small and different quantity of heat at each node (say, a metal mesh)
  - we write a function  $u$ :  $u(i) = \text{heat at } i$
- This heat will spread through the mesh/graph
- Question: how much heat will each node have after a small amount of time?
- “heat” can be representative of the the probability of a random walk being there

# Heat diffusion

- Suppose nodes  $i$  and  $j$  are neighbors
  - How much heat will flow from  $i$  to  $j$ ?

# Heat diffusion

- Suppose nodes  $i$  and  $j$  are neighbors
  - How much heat will flow from  $i$  to  $j$ ?
  - Proportional to the gradient:
    - $u(i) - u(j)$
    - this is signed: negative means heat flows into  $i$

# Heat diffusion

- If  $i$  has neighbors  $j_1, j_2, \dots$
- Then heat flowing out of  $i$  is:
  - $u(i) - u(j_1) + u(i) - u(j_2) + u(i) - u(j_3) + \dots$
  - $\text{degree}(i) \cdot u(i) - u(j_1) - u(j_2) - u(j_3) - \dots$

- Hence  $L = D - A$

$$\begin{bmatrix} 1 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} - \begin{bmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$$

# Laplacian

$$L(u) \approx \frac{\partial u}{\partial t}$$

- The net heat flow out of nodes in a time step
- The change in heat distribution in a small time step
- The rate of change of heat distribution

# Heat flow

$$v[0] = \text{const}$$

- Will eventually converge of  $v[0]$  : the zeroth eigen vector, with eigen value  $\lambda_0 = 0$
- $v[0]$  is a constant: no more flow!

# Laplacian

- Changed represented by  $L$  on any input vector can be represented by sum of action of its eigen vectors (we saw this last time for  $MM^T$ )

- $v[0]$  is the slowest component of the change

- With multiplier

$$\lambda_0 = 0$$

- $v[1]$  is slowest non-zero component

- with multiplier

$$\lambda_1$$

# Spectral gap

$$\lambda_1 - \lambda_0$$

- Determines the overall speed of change
- If the slowest component  $v[1]$  changes fast
  - Then overall the values must be changing fast
  - Fast diffusion

# Application 4: isomorphism testing

- Eigen values different implies graphs are different
- Though not necessarily the other way

# Spectral methods

- Wide applicability inside and outside networks
- Related to many fundamental concepts
  - PCA
  - SVD
  - Random walks, diffusion, heat equation...
- Results are good many times, but not always
- Relatively hard to give provable properties
- Inefficient: eig. computation costly on large matrix
- (Somewhat) efficient methods exist for more restricted problems
  - e.g. when we want only a few smallest/largest eigen vectors
