

End-to-end systems 1: CTC

(Connectionist Temporal Classification)

Peter Bell

Automatic Speech Recognition – ASR Lecture 13
3 March 2025

End-to-end systems

- End-to-end systems are systems which learn to directly map from an input sequence X to an output sequence Y , estimating $P(Y|X)$
 - Y can be a sequence of words or subwords
- ML trained HMMs are kind of end-to-end system – the HMM estimates $P(X|Y)$, and when combined with a language model gives an estimate of $P(Y|X)$
- Sequence discriminative training of HMMs (using GMMs or DNNs) can be regarded as end-to-end
 - But training is quite complicated – need to estimate the denominator (total likelihood) using lattices, first train conventionally (ML for GMMs, CE for NNs) then finetune using sequence discriminative training
 - Lattice-free MMI is one way to address these issues

Fully differentiable end-to-end systems

Approaches based purely on recurrent networks or transformers which directly map input to output sequences

- CTC – Connectionist Temporal Classification
- Encoder-decoder approaches

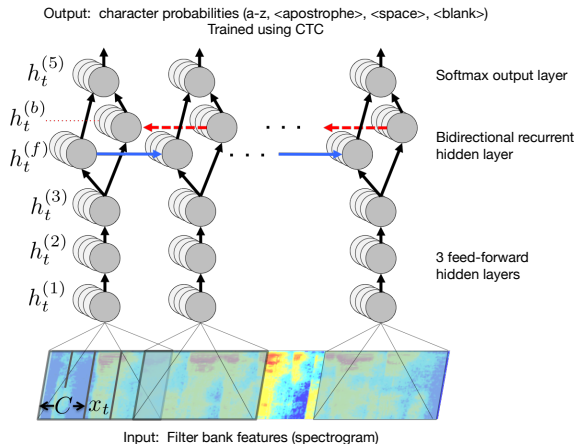

No need for specialised HMM-style decoders (although they can still be used)

Approaches based purely on recurrent networks or transformers which directly map input to output sequences

- **CTC – Connectionist Temporal Classification**
- Encoder-decoder approaches (*next lecture*)

No need for specialised HMM-style decoders (although they can still be used)

Example: Deep Speech

Hannun et al (2014), "Deep Speech: Scaling up end-to-end speech recognition",

<https://arxiv.org/abs/1412.5567>.

Deep Speech: Results

| Model | SWB | CH | Full |
|---|-------------|-------------|-------------|
| Vesely et al. (GMM-HMM BMMI) [44] | 18.6 | 33.0 | 25.8 |
| Vesely et al. (DNN-HMM sMBR) [44] | 12.6 | 24.1 | 18.4 |
| Maas et al. (DNN-HMM SWB) [28] | 14.6 | 26.3 | 20.5 |
| Maas et al. (DNN-HMM FSH) [28] | 16.0 | 23.7 | 19.9 |
| Seide et al. (CD-DNN) [39] | 16.1 | n/a | n/a |
| Kingsbury et al. (DNN-HMM sMBR HF) [22] | 13.3 | n/a | n/a |
| Sainath et al. (CNN-HMM) [36] | 11.5 | n/a | n/a |
| Soltan et al. (MLP/CNN+I-Vector) [40] | 10.4 | n/a | n/a |
| Deep Speech SWB | 20.0 | 31.8 | 25.9 |
| Deep Speech SWB + FSH | 12.6 | 19.3 | 16.0 |

Table 3: Published error rates (%WER) on Switchboard dataset splits. The columns labeled “SWB” and “CH” are respectively the easy and hard subsets of Hub5’00.

Deep Speech Training

- Maps from acoustic frames X to subword sequences Y , where Y is a sequence of characters (in some other CTC approaches, Y can be a sequence of phones)
- CTC loss function
- Makes good use of large training data
 - Synthetic additional training data by jittering the signal and adding noise
- Many computational optimisations
- n-gram language model to impose word-level constraints
- Competitive results on standard tasks

- n-gram language model to impose word-level constraints
- Competitive results on standard tasks

Connectionist Temporal Classification (CTC)

- Train a recurrent network (or transformer) to map from input sequence X to output sequence Y
 - sequences can be different lengths – for speech, input sequence X (acoustic frames) is much longer than output sequence Y (characters or phonemes)
 - CTC does not require frame-level alignment (matching each input frame to an output token)
- CTC sums over all possible alignments (similar to forward-backward algorithm) – “alignment free”
- Possible to back-propagate gradients through CTC loss function

Good overview of CTC: Awni Hannun, “Sequence Modeling with CTC”, *Distill*. <https://distill.pub/2017/ctc>

CTC: Alignment

- Imagine mapping $(x_1, x_2, x_3, x_4, x_5, x_6)$ to $[a, b, c]$
 - Possible alignments: $aaabbc$, $aabbcc$, $abbbbc$, ...
- However
 - Don't always want to map every input frame to an output symbol (e.g. if there is "inter-symbol silence")
 - Want to be able to have two identical symbols adjacent to each other – keep the difference between
- Solve this using an additional *blank* symbol (ϵ)
- CTC output compression
 - 1 Merge repeating characters
 - 2 Remove blanks

Thus to model the same character successively, separate with a blank

- Some possible alignments for $[h, e, l, l, o]$ and $[h, e, l, o]$ given a 10-element input sequence
 - $[h, e, l, l, o]$: $h\epsilon\epsilon\epsilon\ell\ell\epsilon o$; $he\ell\ell\epsilon\epsilon oo$
 - $[h, e, l, o]$: $h\epsilon\epsilon\epsilon\ell\ell\ell lo$; $hh\epsilon\epsilon\epsilon\ell\epsilon oo\epsilon$

CTC: Alignment example

| | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| h | h | e | € | € | l | l | l | € | l | l | o |
|---|---|---|---|---|---|---|---|---|---|---|---|

| | | | | | | | |
|---|---|---|--|---|---|---|---|
| h | e | € | | l | € | l | o |
|---|---|---|--|---|---|---|---|

| | | | | | | | |
|---|---|--|--|---|--|---|---|
| h | e | | | l | | l | o |
|---|---|--|--|---|--|---|---|

| | | | | |
|---|---|---|---|---|
| h | e | l | l | o |
|---|---|---|---|---|

First, merge repeat characters.

Then, remove any € tokens.

The remaining characters are the output.

CTC: Valid and invalid alignments

Consider an output [c, a, t] with an input of length six

Valid Alignments

€ c c € a t

c c a a t t

c a € € € t

Invalid Alignments

c € c € a t

corresponds to
 $Y = [c, c, a, t]$

c c a a t

has length 5

c € € € | t t

missing the 'a'

CTC: Alignment properties

- Monotonic – Alignments are monotonic (left-to-right model); no re-ordering (unlike neural machine translation)
- Many-to-one – Alignments are many-to-one; many inputs can map to the same output
- But a single input cannot map to many outputs – could be a problem for sounds like “th”
- CTC doesn't find a single alignment: it sums over all possible alignments

CTC: Loss function (1)

- Let C be an output label sequence, including blanks and repetitions – same length as input sequence X
- Posterior probability of output labels $C = (c_1, \dots, c_t, \dots, c_T)$ given the input sequence $X = (x_1, \dots, x_t, \dots, x_T)$:

$$P(C|X) = \prod_{t=1}^T P_t(c_t|X)$$

where $P_t(c_t|X)$ is the probability of outputting label c_t at time t

- This is the probability of a single alignment – we need to sum over all alignments consistent with Y

CTC: Loss function (2)

- Let Y be the compressed target output sequence
- Compute the posterior probability of the target sequence $Y = (s_1, \dots, s_m, \dots, s_M)$ ($M \leq T$) given X by summing over the possible CTC alignments:

$$P(Y|X) = \sum_{C \in A(Y)} P(C|X)$$

where A is the set of possible output label sequences C that can be mapped to Y using the CTC compression rules (merge repeated labels, then remove blanks)

- The CTC loss function \mathcal{L}_{CTC} is given by the negative log likelihood of the sum of CTC alignments:

$$\mathcal{L}_{CTC} = -\log P(Y|X)$$

- Various NN architectures can be used for CTC – traditionally used a deep bidirectional LSTM RNN

CTC: Dynamic programming

Perform the sum over alignments, $A(Y)$, using dynamic programming – very similar to the forward algorithm for classic HMMs.

We first define the expanded symbol sequence,

$$Z = (z_1, \dots, z_i, \dots, z_J) = (\epsilon, s_1, \epsilon, s_2, \epsilon, \dots, \epsilon, s_M, \epsilon)$$

(where $J = 2M + 1$)

The forward probability is:

$$\begin{aligned}\alpha_j(t) &= P(z_1, \dots, z_j | X) \\ &= \sum_{(c_1, \dots, c_t) \in A(z_1, \dots, z_j)} P(c_1, \dots, c_t | X)\end{aligned}$$

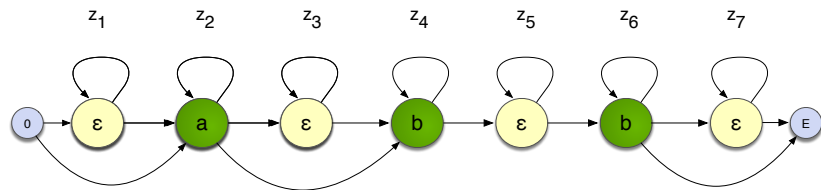

This computes the probability over all label sequences up to time t that are consistent with (z_1, \dots, z_j) .

CTC: HMM topology

We can encode the valid transitions of Z over time using an HMM.

This is a standard left-to-right HMM topology, with the addition of a skip $z_{i-2} \rightarrow z_i$ if $z_i \neq \epsilon$ and $z_i \neq z_{i-2}$

Example for original sequence $Y = [a, b, b]$:

CTC: Forward recursion

- **Initialisation:**

$$\begin{aligned}\alpha_i(0) &= 1 & i &= 1 \\ &= 0 & \text{otherwise}\end{aligned}$$

- **Recursion:**

If $z_i = \epsilon$ or $z_i = z_{i-2}$:

$$\alpha_i(t) = [\alpha_{i-1}(t-1) + \alpha_i(t-1)]p_t(z_i|X)$$

Otherwise:

$$\alpha_i(t) = [\alpha_{i-2}(t-1) + \alpha_{i-1}(t-1) + \alpha_i(t-1)]p_t(z_i|X)$$

- **Termination:**

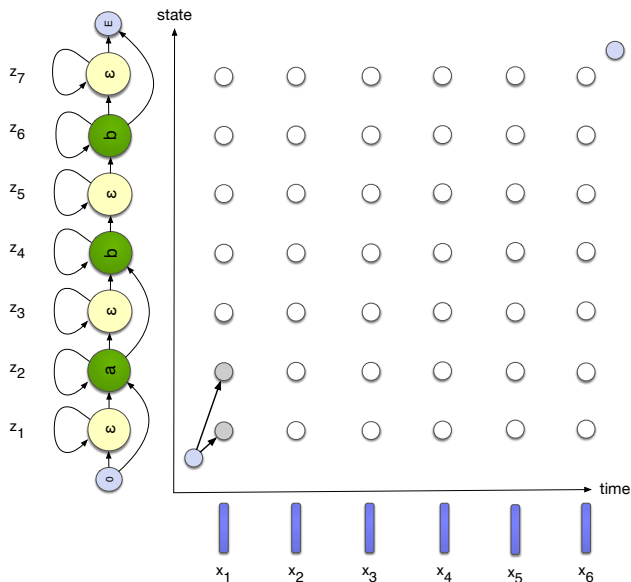

$$P(Z|X) = \alpha_{J-1}(t) + \alpha_J(t)$$

Example

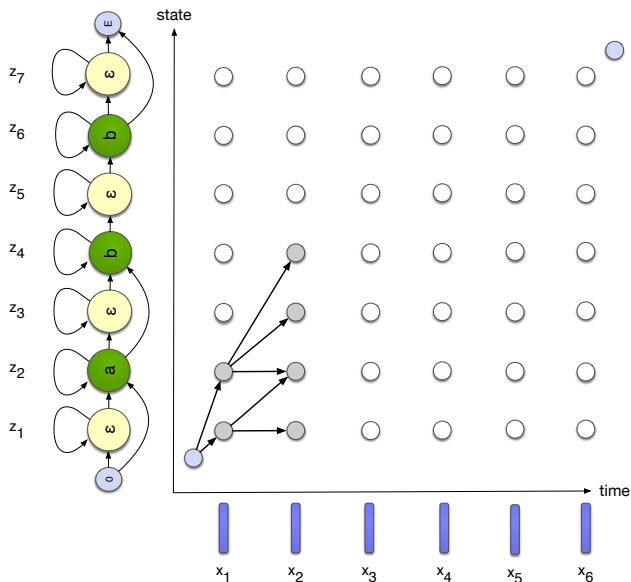

Example alignments for $[a, b, b]$ to an utterance of six frames:

| | | | | | |
|------------|------------|------------|------------|------------|------------|
| a | ϵ | b | ϵ | b | b |
| a | a | ϵ | b | ϵ | b |
| ϵ | a | a | b | ϵ | b |
| ϵ | a | b | ϵ | b | ϵ |
| a | b | ϵ | ϵ | b | b |
| \vdots | \vdots | \vdots | | | |

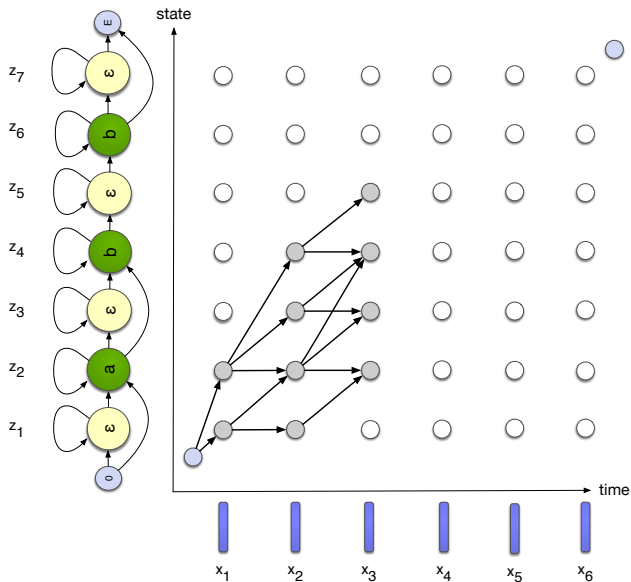

Forward recursion

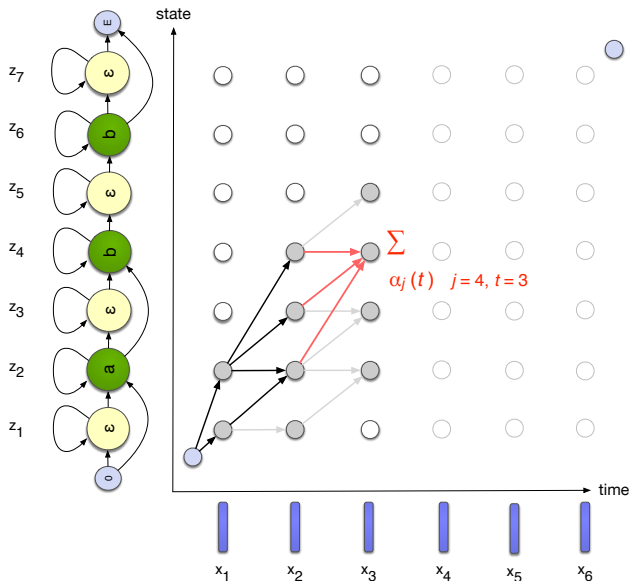

Forward recursion

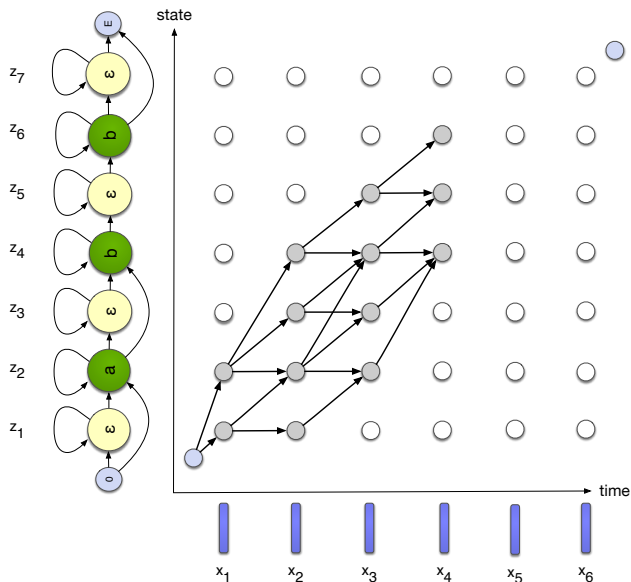

Forward recursion

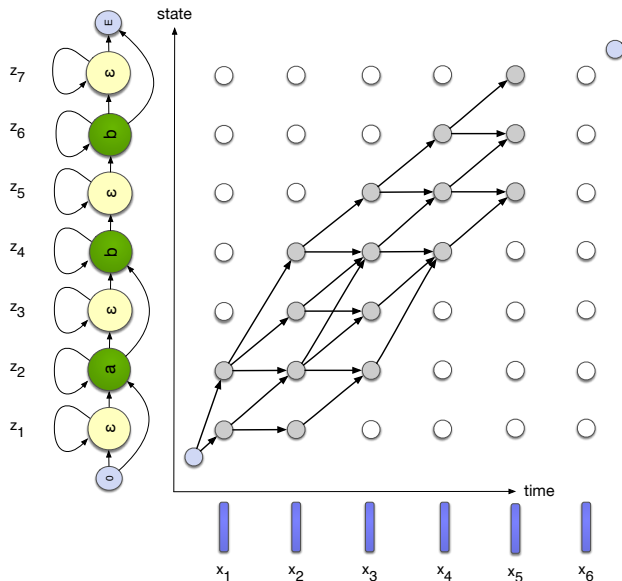

Forward recursion

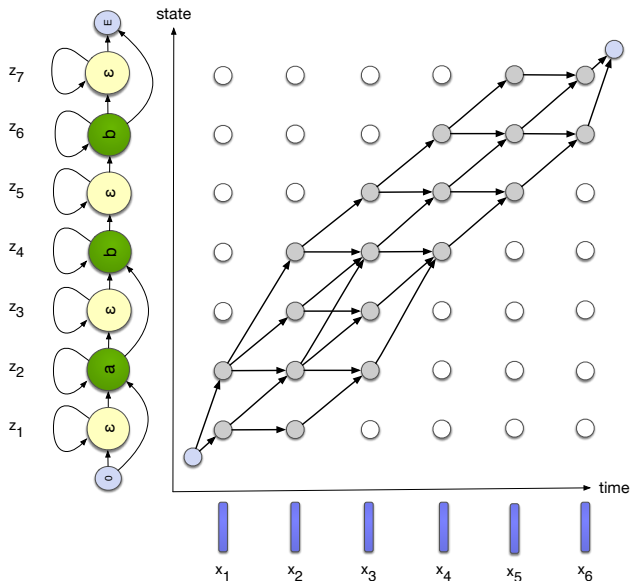

Forward recursion

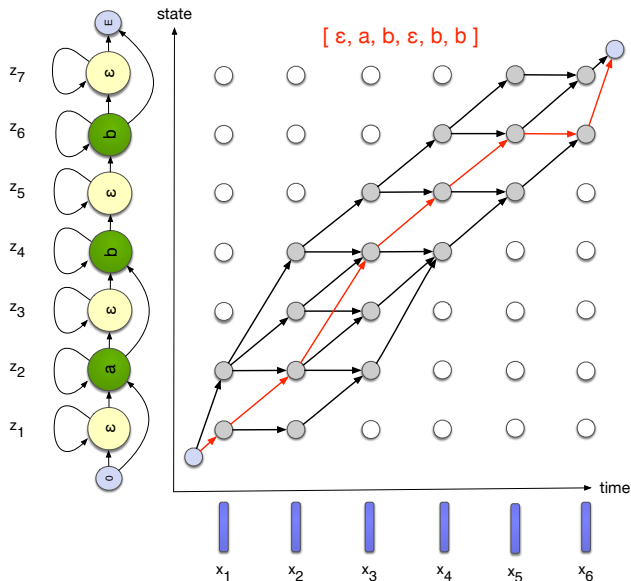

Forward recursion

Forward recursion

One alignment...

Need to solve

$$Y^* = \arg \max_Y P(Y|X)$$

Find best alignment:

$$C^* = \arg \max_C \prod_t^T P(c_t|X)$$

Solve using beam search

CTC: Decoding with beam search

Merge hypotheses

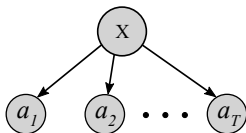

Problem: the best-scoring sequence C^* might not correspond to the overall best Y

Solution: merge hypotheses with the same prefix

Understanding CTC: Conditional independence assumption

- Each output is dependent on the entire input sequence (in Deep Speech this is achieved using a bidirectional recurrent layer)
- Given the inputs, each output is independent of the other outputs (conditional independence)
- CTC does not learn a language model over the outputs, although a language model can be applied later
- Graphical model showing dependencies in CTC:

Applying language models to CTC

- Direct interpolation of a language model with the CTC acoustic model:

$$\hat{W} = \arg \max_W (\log P(Y|X) + \lambda \log P(W)) + \eta L(W))$$

Only consider word sequences W which correspond to the sub-word sequence Y (using a lexicon)

- λ, η are empirically determined scaling factor/insertion bonus
- Lexicon-free CTC: use a sub-word language model $P(Y)$ (Maas et al, 2015)
- WFST implementation: create an FST T which transforms a framewise label sequence \mathbf{c} into the subword sequence Y , then compose with L and G : $T \circ \min(\det(L \circ G))$ (Miao et al, 2015)

- Mozilla have released an Open Source TensorFlow implementation of the Deep Speech architecture:
- <https://hacks.mozilla.org/2017/11/a-journey-to-10-word-error-rate/>
- <https://github.com/mozilla/DeepSpeech>
- Close to state-of-the-art results on librispeech
- Mozilla Common Voice project: <https://voice.mozilla.org/en>

Summary and reading

- CTC is an alternative approach to sequence discriminative training, typically applied to RNN systems
- Used in “Deep Speech” architecture for end-to-end speech recognition
