# Modeling Orientation

- Starting point: Retinotopy model
- Same architecture, different input pattern
- Three dimensions of variance: x, y, orientation
- How will that fit into a 2D map?

## Retinotopy input and response

Retinal activation    LGN response    Iteration 0: Initial V1 response    Iteration 0: Settled V1 response    10,000: Initial V1 response    10,000: Settled V1 response

CMVC figure 4.4

(Reminder from last time)

## Orientation input and response

Retinal activation    LGN response    Iteration 0: Initial V1 response    Iteration 0: Settled V1 response    10,000: Initial V1 response    10,000: Settled V1 response

CMVC figure 5.6

- Multiple activity blobs per input pattern:  
orientation-specific

# Self-organized V1 weights

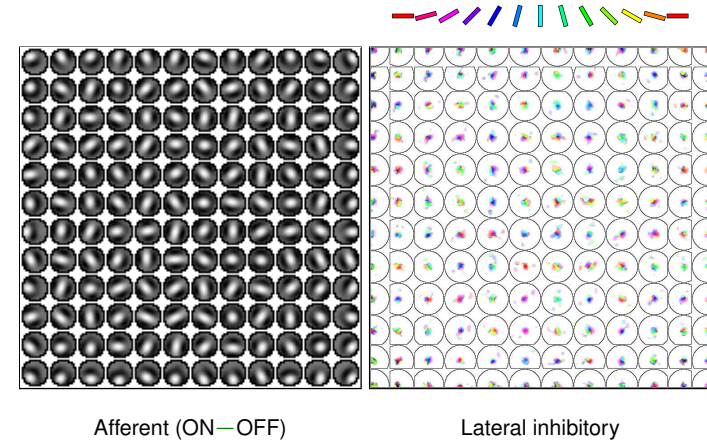

CMVC figure 5.7

Typical:

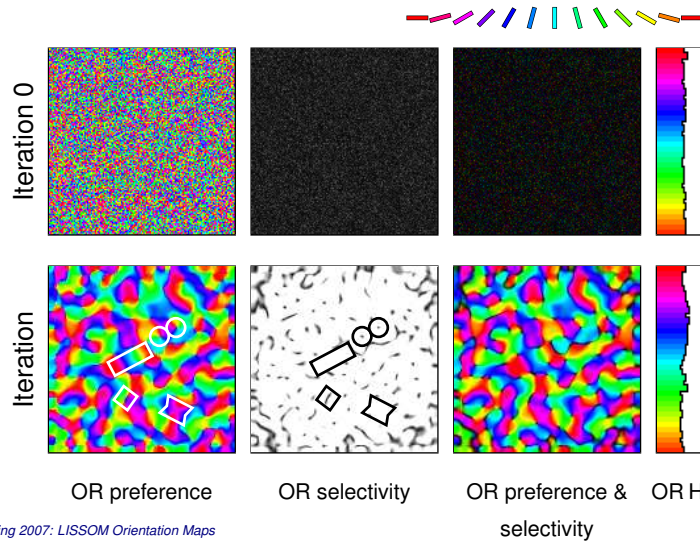

- Gabor-like afferent CF
- Nearly uniform short-range lateral excitatory
- Patchy, orientation-specific long-range lateral inhibitory

# Self-organized weights across V1

CMVC figure 5.8

# OR map self-organization

CMVC figure 5.9

# Macaque ORmap: Fourier, gradient

CMVC figure 5.1

In monkeys:

- Ring-shaped spectrum: repeats regularly in all directions
- High gradient at fractures, pinwheels.

## OR Map: Fourier, gradient

Fourier spectrum

Gradient

LISSOM model has similar spectrum, gradient

CMVC figure 5.10

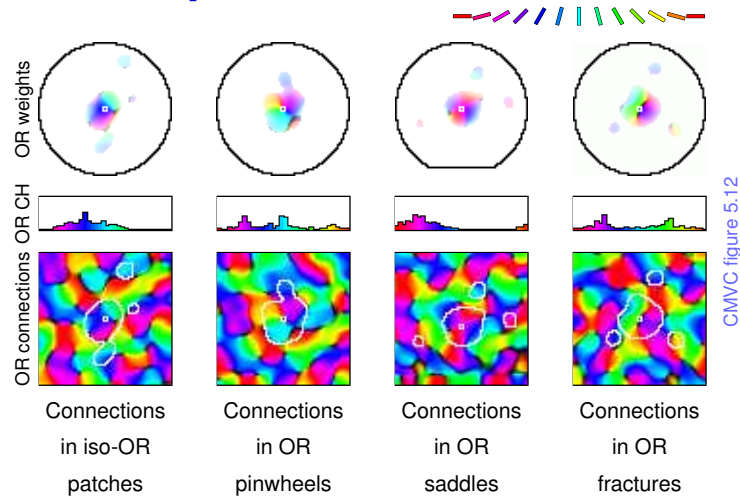

## OR Map: Retinotopic organization

- Retinotopy is distorted locally by orientation prefs
- Matches distortions found in animal maps?

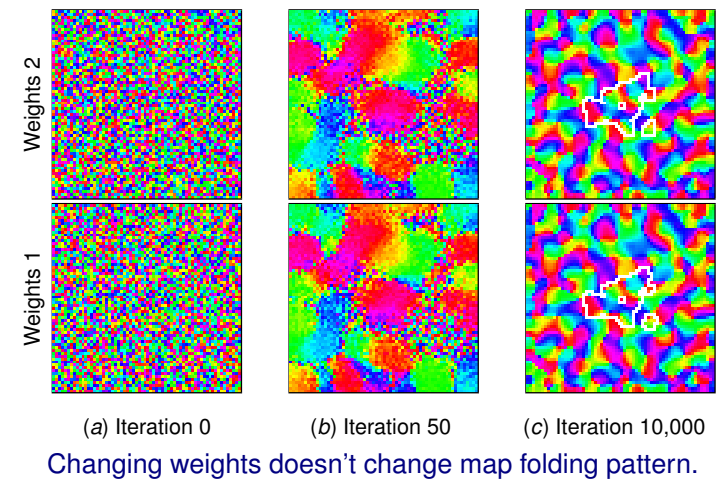

CMVC figure 5.11

## OR Map: Lateral connections

CMVC figure 5.12

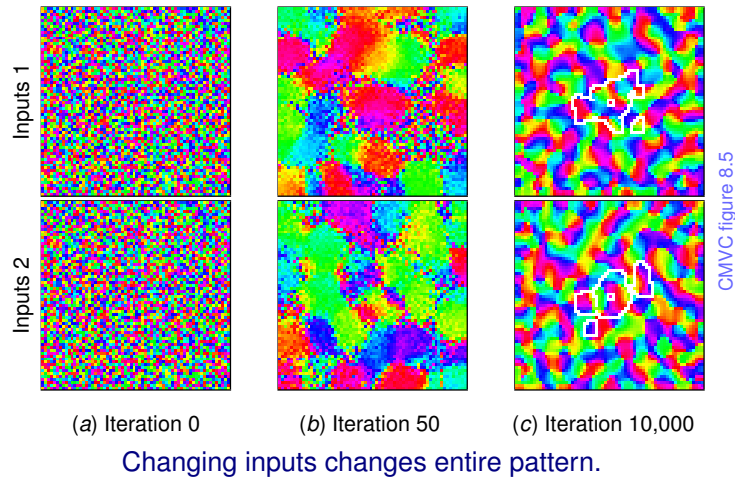

## Effect of initial weights

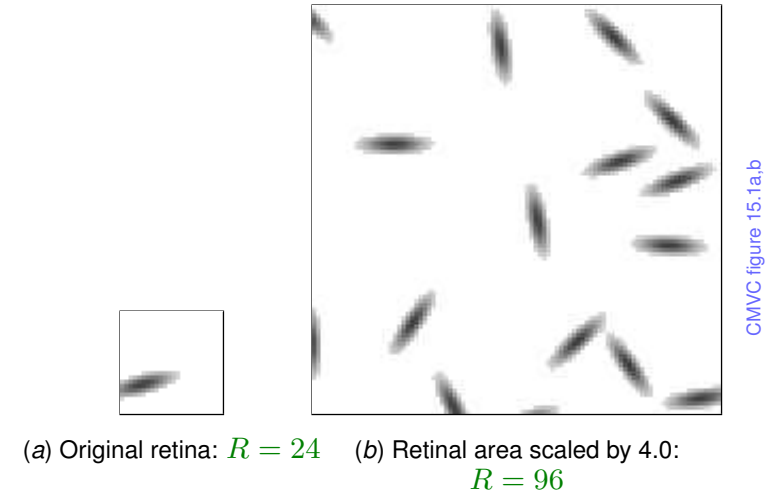

CMVC figure 8.5

Changing weights doesn't change map folding pattern.

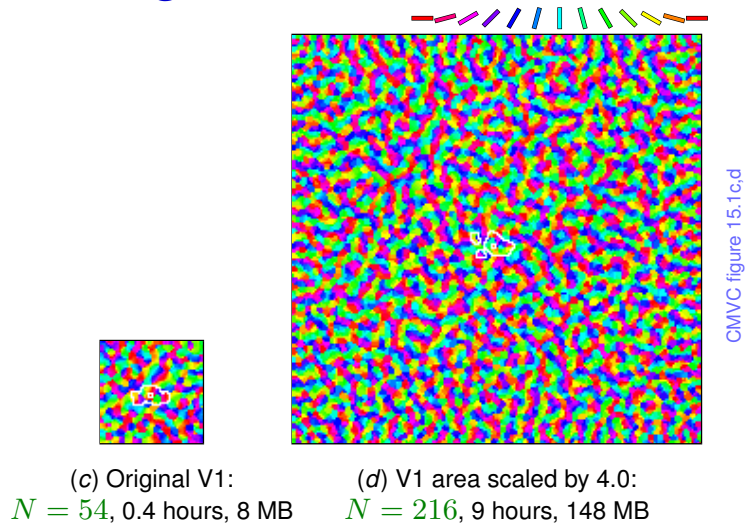

## Effect of input streams

## Scaling retinal and cortical area

## Scaling retinal and cortical area

## Scaling retinal density

## Scaling cortical density

(a)  $36 \times 36$ : 0.17 hours, 2.0 MB  
 (b)  $48 \times 48$ : 0.32 hours, 5.2 MB  
 (c)  $72 \times 72$ : 0.77 hours, 22 MB  
 (d)  $96 \times 96$ : 1.73 hours, 65 MB  
 (e)  $144 \times 144$ : 5.13 hours, 317 MB

CMVC figure 15.3

Above minimum density (due to lateral radii),  
 density not crucial for organization

## Full-size V1 Map

- Map scaled to cover most of visual field
- Allows testing with full-size images
- 30 million connections

## Sample Image

## LGN Response

## V1 Response with $\gamma_n$

## V1 Orientation Map

## Afferent normalization

Mechanism for contrast invariant tuning:

$$s_{ij} = \frac{\gamma_A \left( \sum_{\rho ab} \xi_{\rho ab} A_{\rho ab, ij} \right)}{1 + \gamma_n \left( \sum_{\rho ab} \xi_{\rho ab} \right)}, \quad (1)$$

$\xi_{\rho ab}$ : activation of unit  $(a, b)$  in afferent RF  $\rho$  of neuron  $(i, j)$

$A_{ab, ij}$  is the corresponding afferent weight

$\gamma_A, \gamma_n$  are constant scaling factors

## LGN response to large image

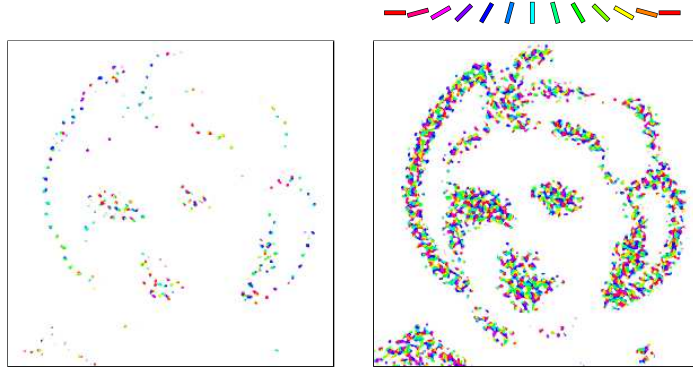

Retinal activation

LGN response

LGN responds to most of the visible contours

## V1 without afferent normalization

CMVC figure 8.2c-e

V1 response:  
 $\gamma_n = 0, \gamma_A = 3.25$

V1 response:  
 $\gamma_n = 0, \gamma_A = 7.5$

Cannot get selective response to all contours

## V1 with afferent normalization

CMVC figure 8.2c-e

V1 response:  
 $\gamma_n = 0, \gamma_A = 3.25$

V1 response:  
 $\gamma_n = 80, \gamma_A = 30$

Responds based on contour, not contrast

## Tuning with afferent normalization

CMVC figure 8.3

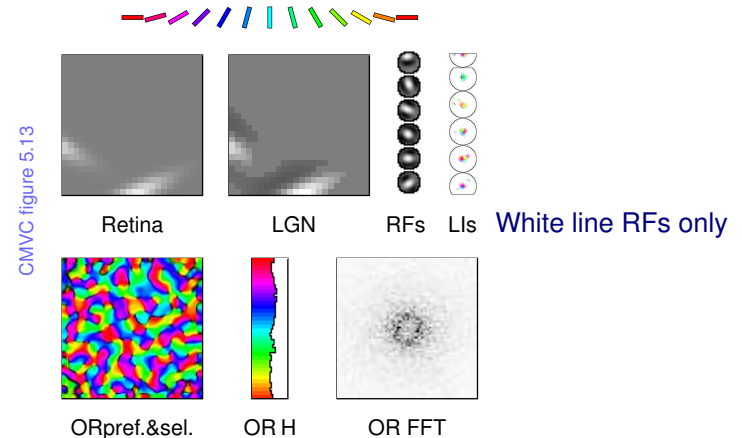

$\gamma_n = 0, \gamma_A = 3.25$

$\gamma_n = 80, \gamma_A = 30$

Sine grating tuning curve:

- Without  $\gamma_n$ : selectivity lost as contrast increases
- With  $\gamma_n$ : always orientation-specific

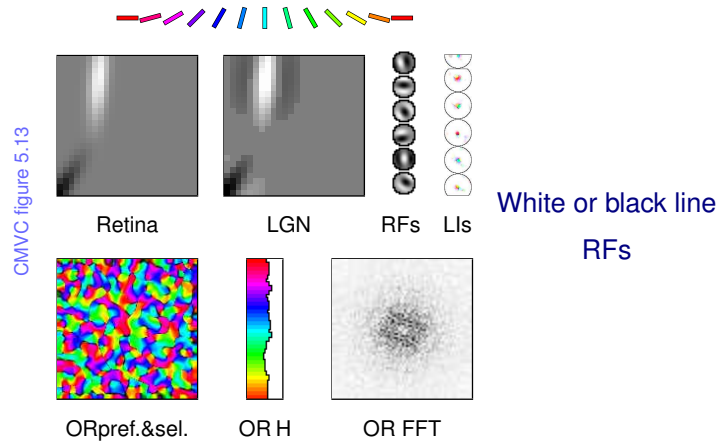

## OR Map: Gaussian

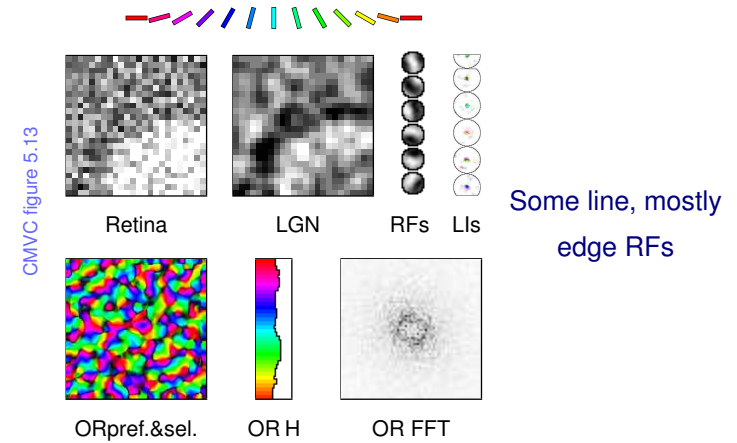

CMVC figure 5.13

White line RFs only

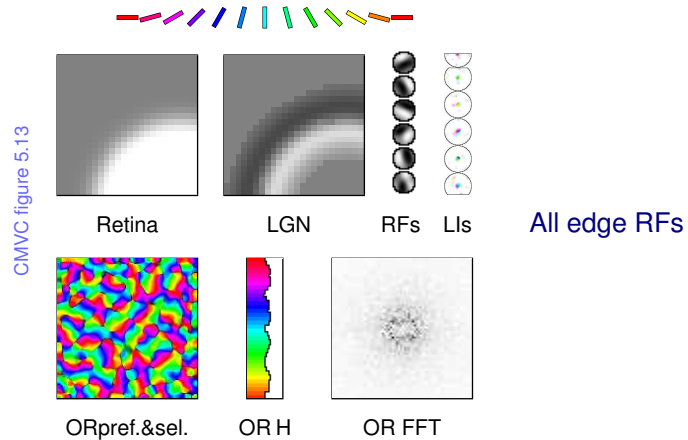

## OR Map: +/- Gaussian

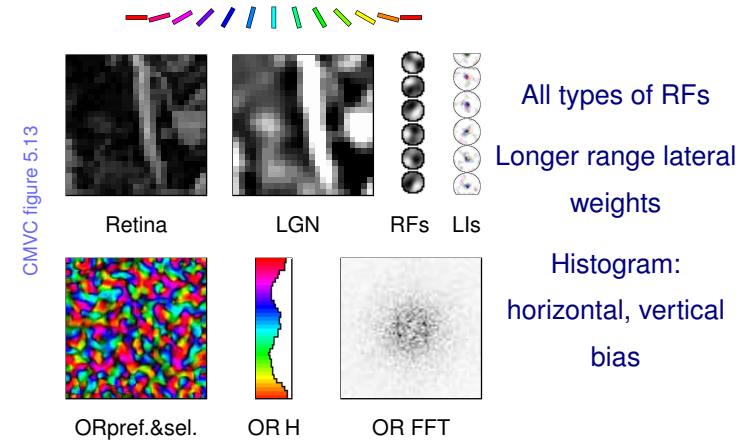

## OR Map: Retinal wave model

## OR Map: Smooth disks

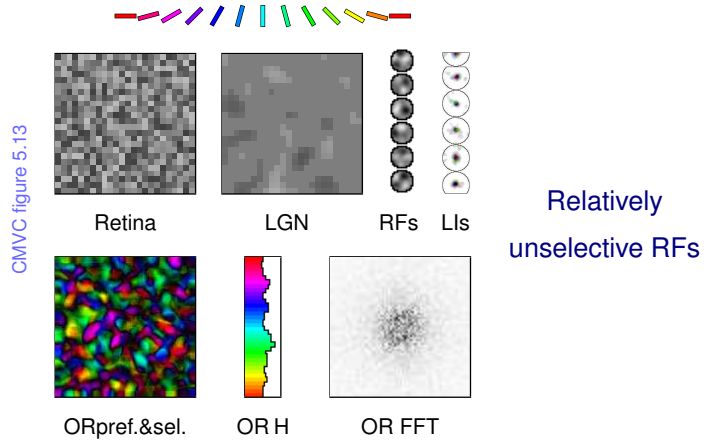

## OR Map: Natural images

## OR Map: Uniform noise

## Modeling pre/post-natal phases

- **Prenatal:** internal activity
- **Postnatal:** natural images (Shouval et al. 1996)

## Pre/post-natal V1 development

- Neonatal map smoothly becomes more selective

## Statistics drive development

- Biased image dataset: mostly landscapes
- Smoothly changes into horizontal-dominated map

## OR Histograms

HLISSOM model

Adult ferret V1  
(Coppola et al. 1998)

- After postnatal training on Shouval natural images, orientation histogram matches results from ferrets
- Model adapts to statistical structure of images

## Summary

- Development depends on the features of the input pattern
- Orientation maps develop with many different input patterns
- Develops Gabor-type RFs with most inputs
- Breaks up image into oriented patches
- Response must be scaled by local contrast to work well for large images
- Matching biology requires prenatal, postnatal phases
