#### The LISSOM Cortical Model

Dr. James A. Bednar

#### **Problems with SOMs**

A Kohonen SOM is very limited as a model of cortical function:

- Picking one winner is valid only for a very small patch with very strong lateral inhibition.
- Full connectivity is possible only for very small cortical networks.
- Lateral interactions are forced to be isotropic, contrary to biological evidence.
- Euclidean distance metric is not clearly relatable to neural firing or synaptic plasticity.

#### **Problems with SOM retinotopy**

The particular model of SOM retinotopy we've been looking at also has other problems:

- There is no known state when the connections from the eye are evenly distributed across a target region; even the initial connections are retinotopic.
- The overall retinotopy is established by axons following gradients of signaling molecules such as Ephrins, though activity may have some role in this process (reviewed in Flanagan 2006; Huberman et al. 2008).

In any case, activity appears to be required for map refinement, and it's interesting that in principle an unfolding process like in the SOM simulation could work.

#### **LISSOM**

The LISSOM model (Sirosh & Miikkulainen 1994) was designed to remove some of the artificial limitations and biologically unrealistic features of a SOM:

- Recurrent lateral interactions, instead of global winner
- Specific lateral connections, instead of isotropic neighborhood
- Spatially localized RFs, instead of full connectivity
- Activation by sigmoided dot product, rather than Euclidean distance
- Learning by Hebbian rule

#### **GCAL**

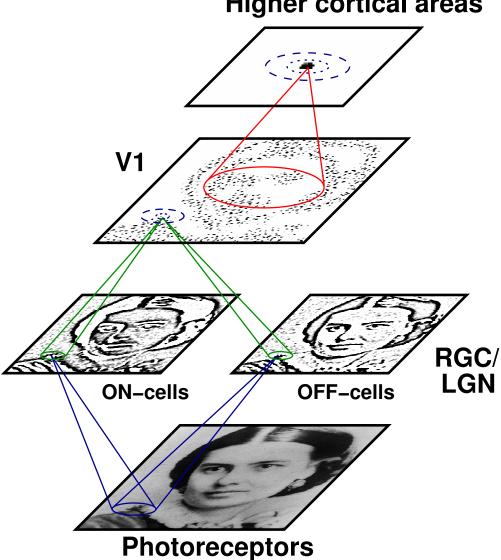

In turn, GCAL (Bednar 2012; Law et al. 2011) was designed to remove some of the artificial limitations and biologically unrealistic features of LISSOM:

- Automatic homeostatic plasticity, instead of hand-adjusted thresholds
- No lateral connection radius shrinking
- Gain control for realistic behavior with contrast (similar to the afferent normalization of CMVC section 8.2.3)

GCAL is otherwise like LISSOM. The CMVC book and older work all focus on LISSOM, but current work uses GCAL; in most cases the distinction is not important.

#### **HLISSOM Architecture**

#### **Higher cortical areas**

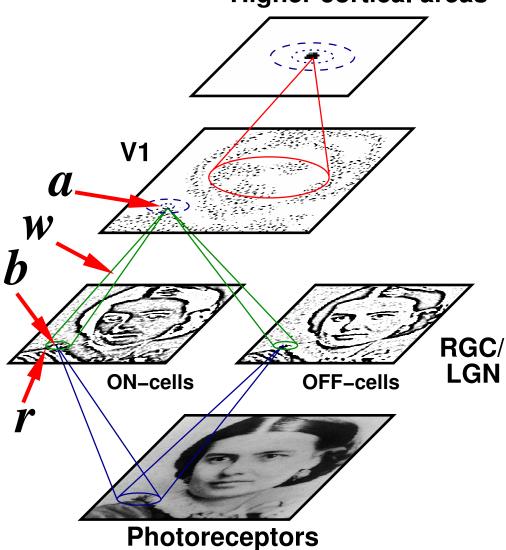

Bednar & Miikkulainen, 1995-2004

Preference maps, receptive fields, patchy lateral connections, multiple areas, natural images

#### **HLISSOM Architecture**

#### **Higher cortical areas**

Activity: thresholded weighted sum of all receptive fields

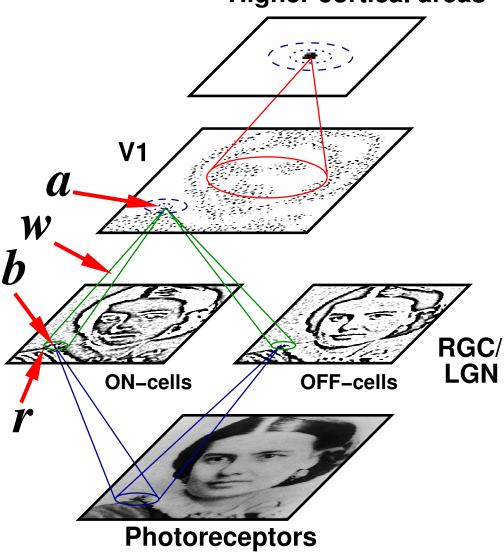

$$\eta_a =$$

$$\sigma\left(\sum_{r}\gamma_{r}\sum_{b}X_{rb}w_{a,rb}
ight)$$

Response highwhen input matchesweights

#### **HLISSOM Architecture**

#### **Higher cortical areas**

#### **Learning:**

normalized Hebbian

$$w_{a,rb}(t+1) =$$

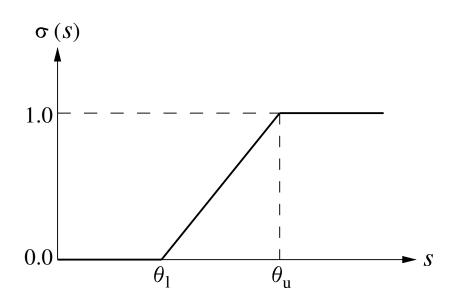

$$rac{w_{a,rb}(t) + lpha_r \eta_a X_{rb}}{\sum_c [w_{a,rc}(t) + lpha_r \eta_a X_{rc}]}$$

- Coactivation →strong connection
- Normalization:

distributes strength

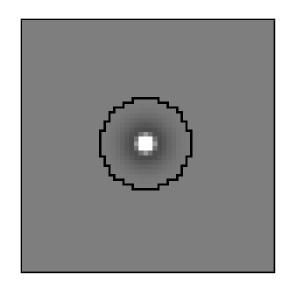

# CMVC figure 4.5

## Neuron activation function $\sigma(s)$

- Piecewise-linear approximation to a sigmoid
- Easy to compute
- Speeds up computation, since most neurons are truly off
- Strongly sensitive to threshold  $\theta_l$

#### DoG RGC/LGN RFs

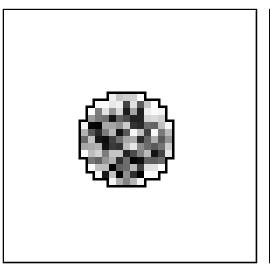

CMVC figure 4.2

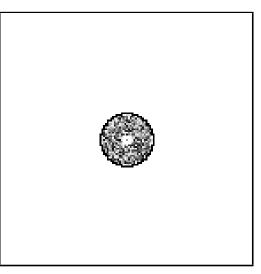

ON neuron

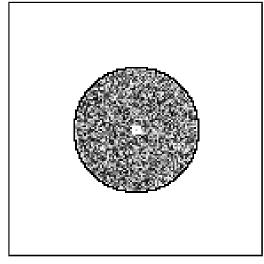

OFF neuron

- Fixed Difference of Gaussians
- Center/surround size ratio based on experimental data
- Precisely balanced c/s strength ratio (not quite realistic)

### **Initial V1 weights**

CMVC figure 4.3

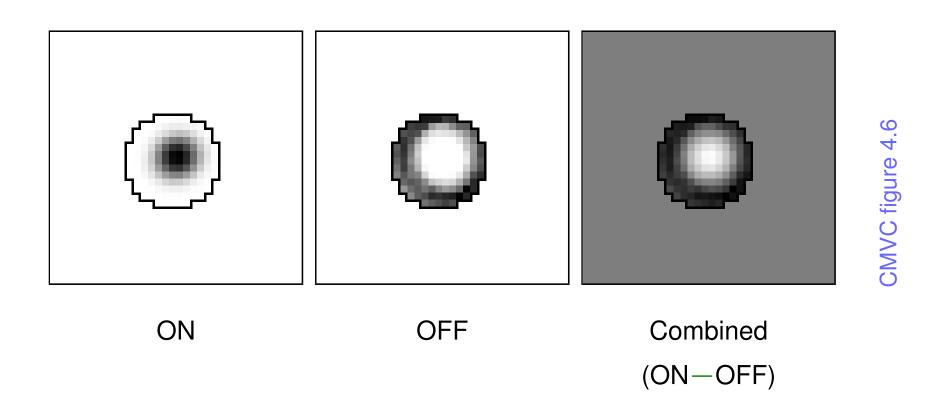

Afferent (ON and OFF)

Lateral excitatory

Lateral inhibitory

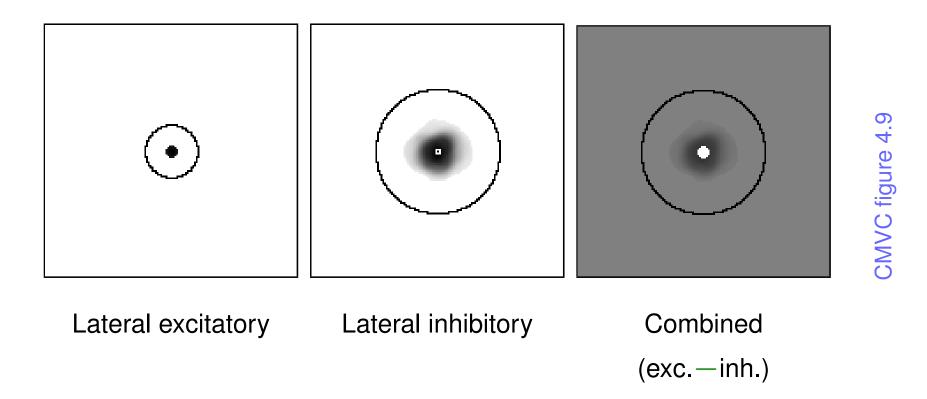

- Initial rough topographic organization
- Explicit lateral connections

## Self-organized V1 afferent weights

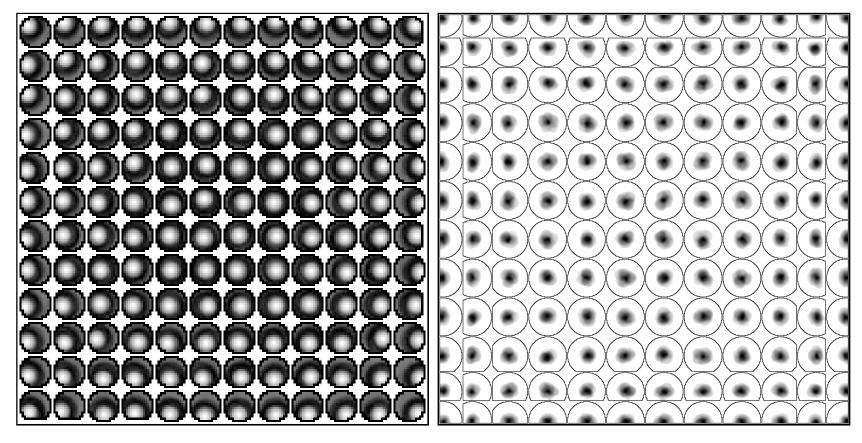

Given isotropic Gaussians, learns isotropic Gaussians

## Self-organized V1 lateral weights

- Learns isotropic (Mexican-hat) lateral interactions
- Reflects the flatness of learned map (no folding)

## Self-organized afferent and lateral weights across V1

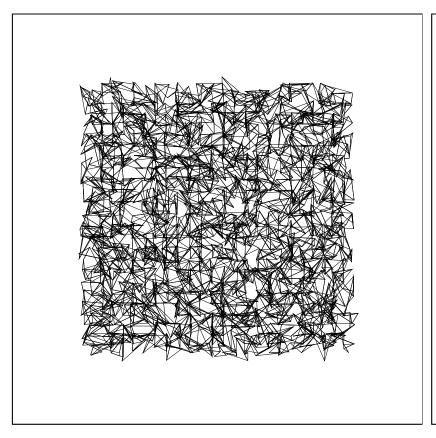

CMVC figure 4.7

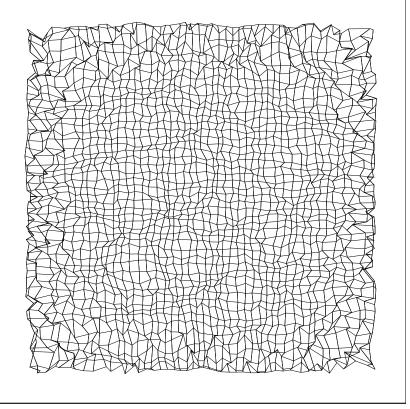

Afferent (ON—OFF)

Lateral inhibitory

## CMVC figure 4.8

## Self-organization of the retinotopic map

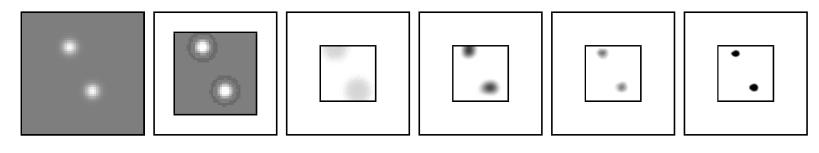

Initial disordered map

Final retinotopic map

# **CMVC figure 4.4**

### Retinotopy input and response

Retinal LGN Iteration 0: Iteration 0: 10,000: 10,000: activation response Initial V1 Settled V1 Initial V1 Settled V1 response response response response

- Settling process: Sharpens activity around strongly activated patches
- Multiple winners occur for multiple features on input

### **Summary**

LISSOM: same basic process as a SOM, but:

- More plausible
- More powerful:
  - Multiple winners
  - Specific lateral connections
- More sensitive to parameters
- More computation and memory intensive
