### Compiler Optimisation 13 – Adaptive and Profile Directed Compilation

Hugh Leather IF 1.18a hleather@inf.ed.ac.uk

Institute for Computing Systems Architecture School of Informatics University of Edinburgh

2019

## Introduction

- Why we fail to optimise
- Profile directed compilation

▲□▶ ▲圖▶ ▲臣▶ ★臣▶ ―臣 …の�?

- Iterative compilation
- A bit of stats

## Why we fail

- Optimisation space is big. <sup>1</sup>
  - Compiler options  $10^{400+}$  per file alone!
  - Consider choices made per function, block, instruction
  - Some choices make more choices e.g. inlining, unrolling

<sup>&</sup>lt;sup>1</sup>You just won't believe how vastly, hugely, mind-bogglingly big it is. I mean, you may think it's a long way down the road to the chemist's, but that's just peanuts to space.

# Why we fail

- Modern architectures very complicated
  - Huge number of components
  - Non deterministic cache and O-O

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

• Different one every few weeks

# Why we fail

- Runtime data not known
  - Can't tell what code paths executed

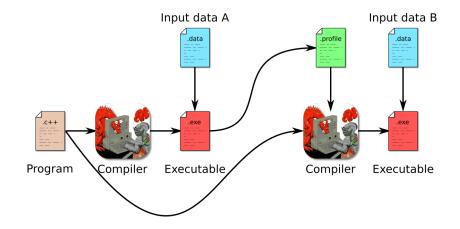

▲□▶ ▲圖▶ ▲臣▶ ★臣▶ ―臣 …の�?

- Can't tell cache miss frequencies
- Can't tell lots of stuff

#### Profile Directed Compilation Profile Guided Optimisation

- Run program with *representative* inputs
- Collect interesting info
- Recompile using interesting info
- Costly
- What if not representative inputs?

# Profile Directed Compilation

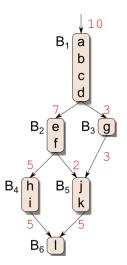

<□▶ <□▶ < □▶ < □▶ < □▶ = □ の < ○

# Profile Directed Compilation

Typically record CFG edge frequencies

- Already seen in insn scheduling
- Also for spill costs in reg alloc
- Also BB layout
- Also inlining costs
- Many others potentially
- But, most compilers do very little

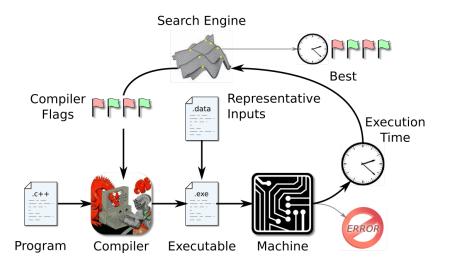

イロト イポト イヨト イヨト

#### Profile Directed Compilation Beyond edge frequencies

- Typically gains small
- Challenge of undecidability and processor behaviour not addressed
- What happens if data changes on the second run?
- Really focuses on persistent control-flow behaviour
- All other information e.g. runtime values, memory locations accessed ignored

• Can we get more out of knowing data and its impact on program behaviour?

#### Iterative Compilation Adaptive Compilation

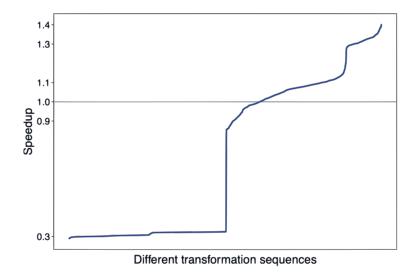

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへで

#### Iterative Compilation Adaptive Compilation

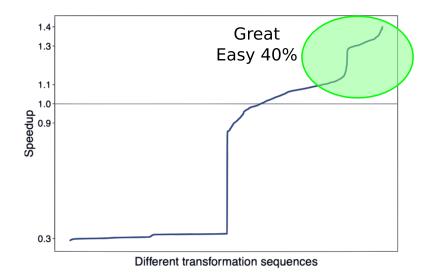

- Avoids thinking about right optimisation
- Search space can potentially include every choice
- Architecture, memory behaviour, etc all handled

◆□▶ ◆帰▶ ◆□▶ ◆□▶ □ のQ@

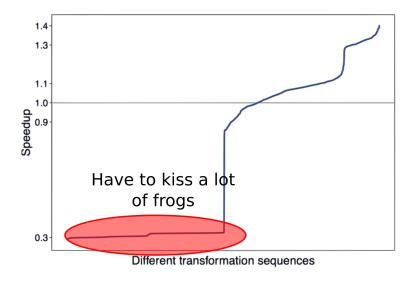

• Performance gains substantial

◆□▶ ◆□▶ ◆三▶ ◆三▶ ◆□ ◆ ◇◇◇

◆□▶ <畳▶ < Ξ▶ < Ξ▶ < □▶ < □▶</p>

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

- Can be very costly thousands of compile/run cycles
- Search techniques can have significant impact on cost
  - Typically Random or Genetic Algorithm
  - But remember No Free Lunch Theorem<sup>2</sup>
- Only iterate over hot code and use minimal inputs
- Check compiler strategies actually change code

#### A Bit of Statistics How to deal with noise

- Most program measurements are noisy (e.g. energy/performance)
  - Other programs
  - OS interaction
  - Small changes in initial state
  - Temperature
  - etc
- Comparisons between measurements not straightforward

#### Random Variable

Variable whose value is subject to chance - e.g. runtime

#### Probability Distribution

Assigns a probability to each value that a random variable may take

#### Observation

A particular 'read' of a random variable

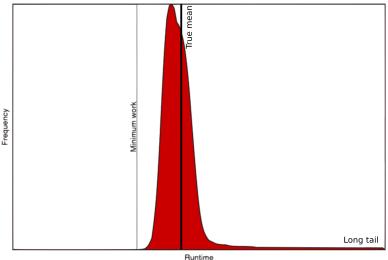

#### Sample

A collection of observations.

#### True vs Sample Mean

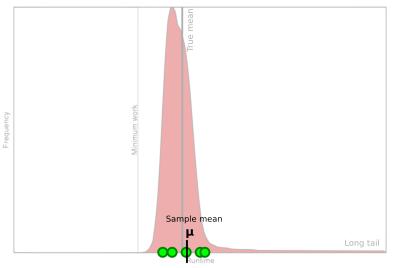

True mean is mean of the underlying distribution Sample mean is mean of a particular sample As  $|Sample| \rightarrow \infty$ , sample mean  $\rightarrow$  true mean

Typical Runtime Distribution

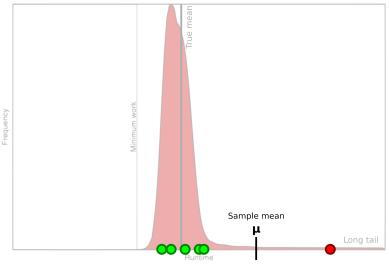

▲□▶ ▲圖▶ ▲臣▶ ★臣▶ ―臣 …の�?

Typical Runtime Distribution

Typical Runtime Distribution

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Pretty sure true mean is somewhere in here

#### Confidence Interval

An interval estimate of a population parameter CI usually has a confidence level, e.g. 95% Converse is significance, i.e. 1 - level

- Typically confidence intervals applied to mean
- Interval does not say "True mean is 95% likely in here" Interpret as "How much do I like this estimate?"
- The more confident want to be about an estimate, the wider the interval
- Large sample size generally gives smaller intervals <sup>3</sup>

- How do we know if sample is big enough?
- $\bullet\,$  If not comparing distributions then use mean  $/\,\,Cl^4$
- If comparing two+ distributions then use statistical tests, e.g. Student's t-test, Anova<sup>5</sup>

<sup>&</sup>lt;sup>4</sup>Strictly speaking, some care must be taken here as this type of sequential sampling plan is not rigorously correct

<sup>&</sup>lt;sup>5</sup>Also take care about this. May need Bonferroni adjustment or otherwise 🗉 🚽

# Summary

- Why we fail to optimise
- Profile directed compilation

▲□▶ ▲圖▶ ▲臣▶ ★臣▶ ―臣 …の�?

- Iterative compilation
- A bit of stats

### EPSRC Centre for Doctoral Training in Pervasive Parallelism

- 4-year programme: MSc by Research + PhD
- Research-focused: Work on your thesis topic from the start
- Collaboration between:
  - University of Edinburgh's School of Informatics
    - \* Ranked top in the UK by 2014 REF
  - Edinburgh Parallel Computing Centre
    - \* UK's largest supercomputing centre

the university of edinburgh

- Research topics in software, hardware, theory and application of:
  - Parallelism
  - Concurrency
  - Distribution
- Full funding available
- Industrial engagement programme includes internships at leading companies

The biggest revolution in the technological landscape for fifty years

Now accepting applications! Find out more and apply at: ervasiveparallelism.inf.ed.ac.ul
