Symmetric encryption schemes

A symmetric cipher consists of two algorithms

- encryption algorithm $E: \mathcal{K} \times \mathcal{M} \to \mathcal{C}$
- decryption algorithm $D: \mathcal{K} \times \mathcal{C} \to \mathcal{M}$

st.
$$\forall k \in \mathcal{K}$$
, and $\forall m \in \mathcal{M}$, $D(k, E(k, m)) = m$

Kerckhoff's principle

- ▶ The encryption (E) and decryption (D) algorithms are public
- ▶ The security relies entirely on the secrecy of the key

Adversarie's capabilities - threat model

The attacker may have access to :

- ightharpoonup some ciphertexts c_1, \ldots, c_n
- ▶ some plaintext/ciphertext pairs $(m_1, c_1), \ldots, (m_n, c_n)$ st. $c_i = E(k, m_i)$
- ▶ an encryption oracle he can maybe trick a user to encrypt messages m_1, \ldots, m_n of his choice
- ▶ a decryption oracle he can maybe trick a user to decrypt ciphertexts c_1, \ldots, c_n of his choice
- ▶ unlimited, or polynomial, or realistic ($\leq 2^{80}$) computational power
- A cryptographic scheme is secure under some assumptions, that is against a certain type of attacker
- A cryptographic scheme may be vulnerable to certain types of attacks but not others

What is a good encryption scheme?

An encryption scheme is secure against a given adversary, if this adversary cannot

- recover the secret key k
- recover the plaintext m underlying a ciphertext c
- recover any bits of the plaintext m underlying a ciphertext c
- **.** . . .

$$\blacktriangleright \mathcal{M} = \mathcal{C} = \mathcal{K} = \{0,1\}^n$$

- ▶ Encryption: $\forall k \in \mathcal{K}$. $\forall m \in \mathcal{M}$. $E(k, m) = k \oplus m$

- ▶ Encryption: $\forall k \in \mathcal{K}$. $\forall m \in \mathcal{M}$. $E(k, m) = k \oplus m$

$$k = 0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 \\ m = 1 & 0 & 0 & 0 & 1 & 0 & 1 & 1 \\ c = 1 & 1 & 1 & 0 & 0 & 0 & 1 & 0 \\ \end{array}$$

- ▶ Encryption: $\forall k \in \mathcal{K}$. $\forall m \in \mathcal{M}$. $E(k, m) = k \oplus m$

▶ Decryption: $\forall k \in \mathcal{K}$. $\forall c \in \mathcal{C}$. $D(k, c) = k \oplus c$

- ▶ Encryption: $\forall k \in \mathcal{K}$. $\forall m \in \mathcal{M}$. $E(k, m) = k \oplus m$

$$k = 0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 \\ m = 1 & 0 & 0 & 0 & 1 & 0 & 1 & 1 \\ c = 1 & 1 & 1 & 0 & 0 & 0 & 1 & 0 \\ \end{array}$$

▶ Decryption: $\forall k \in \mathcal{K}$. $\forall c \in \mathcal{C}$. $D(k, c) = k \oplus c$

$$k = 0 \quad 1 \quad 1 \quad 0 \quad 1 \quad 0 \quad 0 \quad 1$$
 $c = 1 \quad 1 \quad 1 \quad 0 \quad 0 \quad 0 \quad 1 \quad 0$

$$m = 1 \ 0 \ 0 \ 0 \ 1 \ 0 \ 1 \ 1$$

- ▶ Encryption: $\forall k \in \mathcal{K}$. $\forall m \in \mathcal{M}$. $E(k, m) = k \oplus m$

$$k = 0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 \\ m = 1 & 0 & 0 & 0 & 1 & 0 & 1 & 1 \\ c = 1 & 1 & 1 & 0 & 0 & 0 & 1 & 0 \\ \end{array}$$

▶ Decryption: $\forall k \in \mathcal{K}$. $\forall c \in \mathcal{C}$. $D(k, c) = k \oplus c$

$$m = 1 \ 0 \ 0 \ 0 \ 1 \ 0 \ 1 \ 1$$

▶ Consistency: $D(k, E(k, m)) = k \oplus (k \oplus m) = m$

Perfect secrecy

Definition

A cipher (E,D) over $(\mathcal{M},\mathcal{C},\mathcal{K})$ satisfies perfect secrecy if for all messages $m_1,m_2\in\mathcal{M}$ of same length $(|m_1|=|m_2|)$, and for all ciphertexts $c\in\mathcal{C}$

$$|Pr(E(k, m_1) = c) - Pr(E(k, m_2) = c)| \le \epsilon$$

where $k \stackrel{r}{\leftarrow} \mathcal{K}$ and ϵ is some "negligible quantity".

Theorem (Shannon 1949)

The One-Time Pad satisfies perfect secrecy

Theorem (Shannon 1949)

The One-Time Pad satisfies perfect secrecy

<u>Proof:</u> We first note that for all messages $m \in \mathcal{M}$ and all ciphertexts $c \in \mathcal{C}$

$$Pr(E(k, m) = c)$$

Theorem (Shannon 1949)

The One-Time Pad satisfies perfect secrecy

<u>Proof:</u> We first note that for all messages $m \in \mathcal{M}$ and all ciphertexts $c \in \mathcal{C}$

$$Pr(E(k, m) = c) = \frac{\#\{k \in \mathcal{K}: k \oplus m = c\}}{\#\mathcal{K}}$$

Theorem (Shannon 1949)

The One-Time Pad satisfies perfect secrecy

<u>Proof:</u> We first note that for all messages $m \in \mathcal{M}$ and all ciphertexts $c \in \mathcal{C}$

$$Pr(E(k, m) = c) = \frac{\#\{k \in \mathcal{K}: k \oplus m = c\}}{\#\mathcal{K}}$$
$$= \frac{\#\{k \in \mathcal{K}: k = m \oplus c\}}{\#\mathcal{K}}$$

Theorem (Shannon 1949)

The One-Time Pad satisfies perfect secrecy

<u>Proof:</u> We first note that for all messages $m \in \mathcal{M}$ and all ciphertexts $c \in \mathcal{C}$

$$Pr(E(k, m) = c) = \frac{\#\{k \in \mathcal{K}: k \oplus m = c\}}{\#\mathcal{K}}$$
$$= \frac{\#\{k \in \mathcal{K}: k = m \oplus c\}}{\#\mathcal{K}}$$
$$= \frac{1}{\#\mathcal{K}}$$

Theorem (Shannon 1949)

The One-Time Pad satisfies perfect secrecy

<u>Proof:</u> We first note that for all messages $m \in \mathcal{M}$ and all ciphertexts $c \in \mathcal{C}$

$$Pr(E(k, m) = c) = \frac{\#\{k \in \mathcal{K}: k \oplus m = c\}}{\#\mathcal{K}}$$
$$= \frac{\#\{k \in \mathcal{K}: k = m \oplus c\}}{\#\mathcal{K}}$$
$$= \frac{1}{\#\mathcal{K}}$$

where $k \stackrel{r}{\leftarrow} \mathcal{K}$.

Thus, for all messages $m_1, m_2 \in \mathcal{M}$, and for all ciphertexts $c \in \mathcal{C}$

$$|Pr(E(k, m_1) = c) - Pr(E(k, m_2) = c)| \le$$

Theorem (Shannon 1949)

The One-Time Pad satisfies perfect secrecy

<u>Proof:</u> We first note that for all messages $m \in \mathcal{M}$ and all ciphertexts $c \in \mathcal{C}$

$$Pr(E(k,m) = c) = \frac{\#\{k \in \mathcal{K}: k \oplus m = c\}}{\#\mathcal{K}}$$
$$= \frac{\#\{k \in \mathcal{K}: k = m \oplus c\}}{\#\mathcal{K}}$$
$$= \frac{1}{\#\mathcal{K}}$$

where $k \stackrel{r}{\leftarrow} \mathcal{K}$.

Thus, for all messages $m_1, m_2 \in \mathcal{M}$, and for all ciphertexts $c \in \mathcal{C}$

$$|Pr(E(k, m_1) = c) - Pr(E(k, m_2) = c)| \le \left| \frac{1}{\#K} - \frac{1}{\#K} \right| = 0$$

- Key-length!

- Stream cipher invented by Ron Rivest in 1987
- Consists of 2 phases:

- ▶ Main data structure: array *S* of 256 bytes.
- Used in HTTPS and WEP
- Weaknesses of RC4:
 - first bytes are biased
 - → drop the first to 256 generated bytes

- Stream cipher invented by Ron Rivest in 1987
- Consists of 2 phases:

- ▶ Main data structure: array *S* of 256 bytes.
- Used in HTTPS and WEP
- ► Weaknesses of RC4:
 - first bytes are biased
 - → drop the first to 256 generated bytes
 - subject to related keys attacks
 - → choose randomly generated keys as seeds

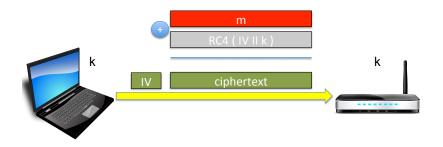

RC4: initialisation

```
for i := 0 to 255 do S[i] := i end j := 0 for i := 0 to 255 do j := (j + S[i] + K[i(\text{mod } |K|)])(\text{mod } 256) swap(S[i], S[j]) end i := 0 j := 0
```

RC4: key stream generation

```
while generatingOutput i := i + 1 \pmod{256} j := j + S[i] \pmod{256} swap(S[i], S[j]) output(S[S[i] + S[j] \pmod{256}]) end
```

WEP uses RC4

Initialisation Vector (IV): 24-bits long string

▶ two-time pad attack: IV is 24 bits long, so the key is reused after at most 2²⁴ frames

 \longrightarrow use longer IVs

- ▶ two-time pad attack: IV is 24 bits long, so the key is reused after at most 2²⁴ frames
 - \longrightarrow use longer IVs
- Fluhrer, Mantin and Shamir (FMS) attack (related keys attack):
 - the keys only differ in the 24 bits IV
 - first bytes of key stream known because standard headers are always sent
 - for certain IVs knowing m bytes of key and keystream means you can deduce byte m+1 of key
 - → instead of using related IVs, generate IVs using a PRG

- ▶ two-time pad attack: IV is 24 bits long, so the key is reused after at most 2²⁴ frames
 - \longrightarrow use longer IVs
- Fluhrer, Mantin and Shamir (FMS) attack (related keys attack):

output bit: R[s]

- ▶ Broken LFSR-based stream ciphers:
 - ▶ DVD encryption: CSS (2 LFSRs)
 - GSM encryption: A5 (3 LFSRs)
 - Bluetooth encryption: E0 (4 LFSRs)

 $\mathcal{K} = \{0,1\}^{40}$

- $\mathcal{K} = \{0,1\}^{40}$
- ▶ Data structures: 17-bits LFSR (R_{17}) and 25-bits LFSR (R_{25})

- $\mathcal{K} = \{0,1\}^{40}$
- ▶ Data structures: 17-bits LFSR (R_{17}) and 25-bits LFSR (R_{25})
- ▶ Initialisation: $R_{17} := 1 || K[0 15]$ $R_{25} := 1 || K[16 - 39]$

- $\mathcal{K} = \{0,1\}^{40}$
- ▶ Data structures: 17-bits LFSR (R_{17}) and 25-bits LFSR (R_{25})
- ▶ Initialisation: $R_{17} := 1 || K[0 15]$ $R_{25} := 1 || K[16 - 39]$
- Keystream generation: 1-byte output per round

Can be broken in time 2^{17} . The idea of the attack is as follows:

 Because of structure of MPEG-2, first 20 bytes of plaintext are known

- Because of structure of MPEG-2, first 20 bytes of plaintext are known
- ▶ Hence also first 20 bytes of keystream are known

- Because of structure of MPEG-2, first 20 bytes of plaintext are known
- ▶ Hence also first 20 bytes of keystream are known
- Given output of 17 bit LFSR, can deduce output of 25 bit LFSR by subtraction

- Because of structure of MPEG-2, first 20 bytes of plaintext are known
- Hence also first 20 bytes of keystream are known
- Given output of 17 bit LFSR, can deduce output of 25 bit LFSR by subtraction
- ► Hence try all 2¹⁷ possibilities for 17 bit LFSR and if generated 25 bit LFSR produces observed keystream, cipher is cracked
