Compiling Techniques

Lecture 3: Introduction to Lexical Analysis

Christophe Dubach

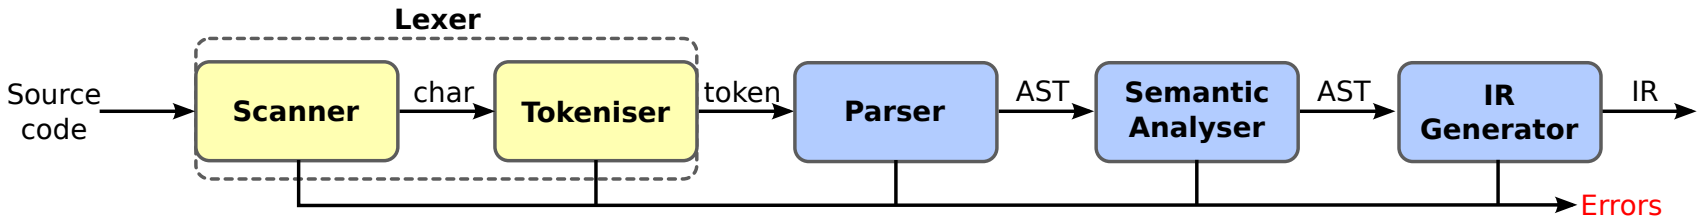
19 September 2019

Reminder

Action

- Create an account and subscribe to the course on piazza.
- Fill up Google form with your name and userid (instructions online on gitlab)

The Lexer



- Maps character stream into words — the basic unit of syntax
- Assign a syntactic category to each work (part of speech)
  - $x = x + y$; becomes ID(x) EQ ID(x) PLUS ID(y) SC
  - word $\cong$ lexeme
  - syntactic category $\cong$ part of speech
  - In casual speech, we call the pair a token
- Typical tokens: number, identifier, $+$, $-$, new, while, if, ...
- Scanner eliminates white space (including comments)

Table of contents

Context-free Language

Context-free syntax is specified with a grammar

- SheepNoise $\rightarrow$ SheepNoise baa | baa
- This grammar defines the set of noises that a sheep makes under normal circumstances

It is written in a variant of BackusNaur Form (BNF)

Formally, a grammar G = (S,N,T,P)

- S is the start symbol
- N is a set of non-terminal symbols
- T is a set of terminal symbols or words
- P is a set of productions or rewrite rules (P:N $\rightarrow$ N $\cup$ T)

Example

```
1  goal  →  expr
2  expr  →  expr op term
3        |  term
4  term  →  number
5        |  id
6  op    →  +
7        |  −
```

$S = goal$
$T = \{number, id, +, -\}$
$N = \{goal, expr, term, op\}$
$P = \{1, 2, 3, 4, 5, 6, 7\}$

- This grammar defines simple expressions with addition & subtraction over “number” and “id”
- This grammar, like many, falls in a class called “context-free grammars”, abbreviated CFG

Regular Expression

Grammars can often be simplified and shortened using an augmented BNF notation where:

- $x*$ is the Kleene closure : zero or more occurrences of x
- $x+$ is the positive closure : one or more occurrences of x
- $[x]$ is an option: zero or one occurrence of x

Example: identifier syntax

```
identifier ::= letter (letter | digit)*
digit      ::= "0" | ... | "9"
letter     ::= "a" | ... | "z" | "A" | ...| "Z"
```

Exercise: write the grammar of signed natural number

Regular Language

Definition

A language is regular if it can be expressed with a single regular expression or with multiple non-recursive regular expressions.

- Regular languages can used to specify the words to be translated to tokens by the lexer.
- Regular languages can be recognised with finite state machine.
- Using results from automata theory and theory of algorithms, we can automatically build recognisers from regular expressions.

Regular language to program

Given the following:

- c is a lookahead character;
- next() consumes the next character;
- error () quits with an error message; and
- first (exp) is the set of initial characters of exp.

Regular language to program

Then we can build a program to recognise a regular language if the grammar is left-parsable.

RE	**pr(RE)**
"x"	`if (c == 'x') next() else error();`
(exp)	`pr(exp);`
$[exp]$	`if (c in first(exp)) pr(exp);`
$exp*$	`while (c in first(exp)) pr(exp);`
$exp+$	`pr(exp); while (c in first(exp)) pr(exp);`
$fact_1 \ldots fact_n$	`pr(fact1); ... ; pr(factn);`

$term_1 \mid \ldots \mid term_n$	`switch (c) {`
	`  case c in first(term1) : pr(term1);`
	`  case ... : ... ;`
	`  case c in first(termn) : pr(termn);`
	`  default : error();`
	`}`

Definition: left-parsable

A grammar is left-parsable if:

$term_1 \mid \ldots \mid term_n$	The terms do not share any initial symbols.
$fact_1 \ldots fact_n$	If $fact_i$ contains the empty symbol then $fact_i$ and $fact_{i+1}$ do not share any common initial symbols.
$[exp], exp*$	The initial symbols of exp cannot contain a symbol which belong to the first set of an expression following exp.

Example: Recognising identifiers

```
void ident() {
  if (c is in [a–zA–Z])
    letter();
  else
    error();
  while (c is in [a–zA–Z0–9]) {
    switch (c) {
      case c is in [a–zA–Z] : letter();
      case c is in [0–9] : digit();
      default : error();
    }
  }
}
void letter() {...}
void digit() {...}
```

Example: Simplified Java version

```
void ident() {
  if (Character.isLetter(c))
    next();
  else
    error();
  while (Character.isLetterOrDigit(c))
    next();
}
```

Role of lexical analysiser

The main role of the lexical analyser (or lexer) is to read a bit of the input and return a lexeme (or token).

```
class Lexer {
  public Token nextToken() {
    // return the next token, ignoring white spaces
  }
  ...
}
```

White spaces are usually ignored by the lexer. White spaces are:

- white characters (tabulation, newline, ...)
- comments (any character following "//" or enclosed between "/*" and "*/"

What is a token?

A token consists of a token class and other additional information.

Example: some token classes

IDENTIFIER	→	foo, main, cnt, ...
NUMBER	→	0, −12, 1000, ...
STRING_LITERAL	→	"Hello world!", "a", ...
EQ	→	==
ASSIGN	→	=
PLUS	→	+
LPAR	→	(
...	→	...

```
class Token {
  TokenClass tokenClass; // Java enumeration
  String data;           // stores number or string
  Position pos;          // line/column number in source
}
```

Example

Given the following C program:

```
int foo(int i) {
  return i+2;
}
```

the lexer will return:

```
INT IDENTIFIER("foo") LPAR INT IDENTIFIER("i") RPAR LBRA
  RETURN IDENTIFIER("i") PLUS NUMBER("2") SEMICOLON
RBRA
```

A Lexer for Simple Arithmetic Expressions

Example: BNF syntax

```
identifier ::= letter (letter | digit)*
digit      ::= "0" | ... | "9"
letter     ::= "a" | ... | "z" | "A" | ... | "Z"
number     ::= digit+
plus       ::= "+"
minus      ::= "-"
```

Example: token definition

```
class Token {

    enum TokenClass {
        IDENTIFIER
        NUMBER,
        PLUS,
        MINUS,
    }

    // fields
    final TokenClass tokenClass;
    final String data;
    final Position position;

    // constructors
    Token(TokenClass tc) {...}
    Token(TokenClass tc, String data) {...}
    ...
}
```

Example: tokeniser implementation

```
class Tokeniser {

  Scanner scanner;

  Token next() {

    char c = scanner.next();

    // skip white spaces
    if (Character.isWhitespace(c)) return next();

    if (c == '+') return new Token(TokenClass.PLUS);
    if (c == '-') return new Token(TokenClass.MINUS);

    // identifier
    if (Character.isLetter(c)) {
      StringBuilder sb = new StringBuilder();
      sb.append(c);
      c = scanner.peek();
      while (Character.isLetterOrDigit(c)) {
        sb.append(c);
        scanner.next();
        c = scanner.peek();
      }
      return new Token(TokenClass.IDENTIFIER, sb.toString());
    }
```

Example: continued

```
    // number
    if (Character.isDigit(c)) {
      StringBuilder sb = new StringBuilder();
      sb.append(c);
      c = scanner.peek();
      while (Character.isDigit(c)) {
        sb.append(c);
        scanner.next();
        c = scanner.peek();
      }
      return new Token(TokenClass.NUMBER, sb.toString());
    }

  }

}
```

Some grammars are ambiguous.

Example 1

```
comment ::= "/*" .* "*/" | "//" .* NEWLINE
div     ::= "/"
```

Solution:

Longest matching rule

The lexer should produce the longest lexeme that corresponds to the definition.

coursework hint: use peek ahead function from the Scanner

Some grammars are ambiguous.

Example 2

```
number      ::= ["-"] digit+
digit       ::= "0" | ... | "9"
plus        ::= "+"
minus       ::= "-"
```

Solution:

Delay to parsing stage

Remove the ambiguity and deal with it during parsing

```
number      ::= digit+
digit       ::= "0" | ... | "9"
plus        ::= "+"
minus       ::= "-"
```
