Tutorial 4: Subtyping and polymorphism

Solution notes

1. Subtyping and type bounds

(a)

$$Sub1 <: Super \quad Sub2 <: Super$$

(b) i. $Sub1 \times Sub2 <: Super \times Super$ This holds:

$$\frac{Sub1 <: Super \quad Sub2 <: Super}{Sub1 \times Sub2 <: Super \times Super}$$

ii. $Sub1 \rightarrow Sub2 <: Super \rightarrow Super$ This does not hold since $Super <: Sub1$ doesn't.

$$\frac{\begin{array}{c} ??? \\ Super <: Sub1 \quad Sub2 <: Super \end{array}}{Sub1 \rightarrow Sub2 <: Super \rightarrow Super}$$

iii. $Super \rightarrow Super <: Sub1 \rightarrow Sub2$ This does not hold since $Super <: Sub2$ doesn't.

$$\frac{\begin{array}{c} ??? \\ Sub1 <: Super \quad Super <: Sub2 \end{array}}{Super \rightarrow Super <: Sub1 \rightarrow Sub2}$$

iv. $Super \rightarrow Sub1 <: Sub2 \rightarrow Super$ This holds:

$$\frac{Sub1 <: Super \quad Sub2 <: Super}{Super \rightarrow Sub1 <: Sub2 \rightarrow Super}$$

v. (*) $(Sub1 \rightarrow Sub1) \rightarrow Sub2 <: (Super \rightarrow Sub1) \rightarrow Super$ This holds:

$$\frac{\begin{array}{c} Sub1 <: Super \quad Sub1 <: Sub1 \\ \hline Super \rightarrow Sub1 <: Sub1 \rightarrow Sub1 \quad Sub2 <: Super \end{array}}{(Sub1 \rightarrow Sub1) \rightarrow Sub2 <: (Super \rightarrow Sub1) \rightarrow Super}$$

- (c) If we call `f1` on `Sub2(true)` then the result has type `Super`. We can't access the `b` field because of a type mismatch.
- (d) This typechecks, because in either case we return `x` which has type `A`. If we apply it to a value of type `Sub1` or `Sub2` we get the same value back. If we apply it to `42 : Int` then we get a match error.
- (e) This typechecks, because as for `f2` we return `x : A` in either case. However, now if we apply to `Sub1` or `Sub2` we get the same value back, while if we apply to something of an unrelated type we get a type error. This seems to solve the problem.

2. Typing derivations

Construct typing derivations for the following expressions, or argue why they are not well-formed:

(a) $\Lambda A. \lambda x:A. x + 1$ does not typecheck because `A` is not `int`.

$$\frac{\begin{array}{c} ??? \\ x:A \vdash x : int \quad x:A \vdash 1 : int \\ \hline x:A \vdash x + 1 : int \\ \vdash \lambda x:A. x + 1 : A \rightarrow int \\ \hline \vdash \Lambda A. \lambda x:A. x + 1 : \forall A. A \rightarrow int \end{array}}{}$$

- (b) (*) $\Lambda A. \lambda x:A \times A. \text{if } \text{fst } x == \text{snd } x \text{ then } \text{fst } x \text{ else } \text{snd } x$ (and how does its well-formedness depend on the typing rule for equality?)

$$\frac{\frac{\frac{\Gamma \vdash x:A \times A}{\Gamma \vdash \text{fst } x : A} \quad \frac{\Gamma \vdash x:A \times A}{\Gamma \vdash \text{snd } x : A} \quad \frac{\Gamma \vdash x:A \times A}{\Gamma \vdash \text{fst } x : A} \quad \frac{\Gamma \vdash x:A \times A}{\Gamma \vdash \text{snd } x : A}}{\Gamma \vdash \text{fst } x == \text{snd } x : \text{bool}} \quad \frac{\Gamma \vdash x:A \times A}{\Gamma \vdash \text{fst } x : A} \quad \frac{\Gamma \vdash x:A \times A}{\Gamma \vdash \text{snd } x : A}}{\Gamma \vdash \text{if } \text{fst } x == \text{snd } x \text{ then } \text{fst } x \text{ else } \text{snd } x : A}$$

$$\frac{\Gamma \vdash \text{if } \text{fst } x == \text{snd } x \text{ then } \text{fst } x \text{ else } \text{snd } x : A}{\vdash \Lambda A. \lambda x:A \times A. \text{if } \text{fst } x == \text{snd } x \text{ then } \text{fst } x \text{ else } \text{snd } x : \forall A. A \times A \rightarrow A}$$

where $\Gamma = x:A \times A$. this only works because we have defined $==$'s typing rule so that any two values of the same type can be compared for equality, including two values of an unknown type A . However, if $==$ is restricted to base types (as in Coursework 1) then we cannot do this.

3. Evaluation derivations

Construct evaluation derivations for the following expressions, or explain why they do not evaluate:

- (a) $(\Lambda A. \lambda x:A. x + 1)[\text{int}]$ 42 Notice that this does not typecheck, but still evaluates OK.

$$\frac{\frac{\Lambda A. \lambda x:A. x + 1 \Downarrow \Lambda A. \lambda x:A. x + 1 \quad \lambda x:\text{int}. x + 1 \Downarrow \lambda x:\text{int}. x + 1}{(\Lambda A. \lambda x:A. x + 1)[\text{int}] \Downarrow \lambda x:\text{int}. x + 1} \quad 42 \Downarrow 42}{(\Lambda A. \lambda x:A. x + 1)[\text{int}] \Downarrow 43}$$

- (b) $(\Lambda A. \lambda x:A. x + 1)[\text{bool}]$ true

This does not typecheck, and does not evaluate either, because when we try to add true to 1 we get stuck.

$$\frac{\frac{(\Lambda A. \lambda x:A. x + 1) \Downarrow (\Lambda A. \lambda x:A. x + 1) \quad \lambda x:\text{bool}. x + 1 \Downarrow \lambda x:\text{bool}. x + 1}{(\Lambda A. \lambda x:A. x + 1)[\text{bool}] \Downarrow \lambda x:\text{bool}. x + 1} \quad \text{true} \Downarrow \text{true}}{\text{true} + 1 \Downarrow \text{??}} \quad \text{true} + 1 \Downarrow \text{??}$$

4. (*) Lists and polymorphism

- (a)

$$\begin{aligned} & \Lambda A. \Lambda B. \lambda f:A \rightarrow B. \text{rec map}(x:\text{list}[A]). \\ & \quad \text{case}_{\text{list}} x \text{ of } \{\text{nil} \Rightarrow \text{nil} ; x :: xs \Rightarrow (fx) :: \text{map}(xs)\} \end{aligned}$$

Notice that the rec only handles the inner function call.

- (b)

$$\frac{\frac{\frac{\vdash \text{map} : \forall A. \forall B. (A \rightarrow B) \rightarrow (\text{list}[A] \rightarrow \text{list}[B])}{\vdash \text{map}[\text{int}] : \forall B. (\text{int} \rightarrow B) \rightarrow (\text{list}[\text{int}] \rightarrow \text{list}[B])}}{\vdash \text{map}[\text{int}][\text{int}] : (\text{int} \rightarrow \text{int}) \rightarrow (\text{list}[\text{int}] \rightarrow \text{list}[\text{int}])} \quad \frac{x:\text{int} \vdash x:\text{int} \quad x:\text{int} \vdash 1 : \text{int}}{x:\text{int} \vdash x + 1 : \text{int}} \quad \frac{\vdash \lambda x:\text{int}. x + 1 : \text{int} \rightarrow \text{int}}{\vdash 2 : \text{int} \quad \vdash \text{nil} : \text{list}[\text{int}]} \quad \frac{}{\vdash (2 :: \text{nil}) : \text{list}[\text{int}]}}{\vdash \text{map}[\text{int}][\text{int}](\lambda x. x + 1) : \text{list}[\text{int}] \rightarrow \text{list}[\text{int}]} \quad \frac{\vdash \text{map}[\text{int}][\text{int}](\lambda x. x + 1)(2 :: \text{nil}) : \text{list}[\text{int}]}{\vdash \text{map}[\text{int}][\text{int}](\lambda x. x + 1)(2 :: \text{nil}) : \text{list}[\text{int}]}$$

- (c) This question is intended to provoke discussion; the answer to this question depends on what “definable” means, which is not a concept we have carefully defined.

In one sense, lists and the list operations are not definable, because there is no way to create a data structure of infinite “size” using just pairs and sums (e.g. for any finite program, we can bound the maximum size of a data structure the program constructs.)

In another reasonable sense, lists could be defined (in principle) by encoding pairs, sums, and lists into natural numbers (assuming infinite precision arithmetic). However, this too might be unsatisfactory, since we would not easily be able to do this uniformly in the type of list elements τ , and it would be very difficult to translate a polymorphic program operating over lists.
