## Today

- Uninformed search: summary
- Informed search,
- Search Heuristics

See Russell and Norvig, Chapters 3,4

## Graph search

The state space with actions leading from state to state corresponds naturally to a graph rather than a tree; the state appears only once in the graph.

There are data structures corresponding to graphs, and graph search algorithms that avoid repetition of states already seen.
The idea is to keep track of nodes that have already been expanded; if search arrives back at such a node, it is ignored in future search.
See Russell and Norvig for details.

## Summary of algorithms

| Criterion | Breadth- <br> First | Uniform- <br> Cost | Depth- <br> First | Depth- <br> Limited | Iterative <br> Deepening |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Complete? | Yes* | Yes* | No | Yes, if $l \geq d$ | Yes |
| Time | $b^{d+1}$ | $b^{\left\lceil C^{*} / \epsilon\right\rceil}$ | $b^{m}$ | $b^{l}$ | $b^{d}$ |
| Space | $b^{d+1}$ | $b^{\left\lceil C^{*} / \epsilon\right\rceil}$ | $b m$ | $b l$ | $b d$ |
| Optimal? | Yes* | Yes* | No | No | Yes |

Here * indicates conditions stated earlier.

## informárontics

## Informed search strategies

Informed strategies use heuristic "rule of thumb" ideas to guide search based on some estimation of where the solution is most likely to be found.
We look at some such strategies:

- Best-first search
- A* search
- Heuristics

## Reminder: Searching a Tree

function Tree-SEARCH ( problem, fringe) returns a solution, or failure
fringe $\leftarrow \operatorname{Insert}($ Make-Node(Initial-State[problem]), fringe)
loop do
if fringe is empty then return failure
node $\leftarrow$ Remove-Front(fringe)
if Goal-Test [problem] applied to State(node) succeeds return node
fringe $\leftarrow \operatorname{InsertALL}(\operatorname{Expand}($ node, problem $)$, fringe)

A strategy is defined by picking the order of node expansion

## informatron oftics

## Romania with step costs in km

Use a straight line heuristic: distance to goal in straight line.

| Arad | 366 | Mehadia | 241 |
| :--- | ---: | :--- | ---: |
| Bucharest | 0 | Neamt | 234 |
| Craiova | 160 | Oradea | 380 |
| Dobreta | 242 | Pitesti | 100 |
| Eforie | 161 | Rimnicu Vilcea | 193 |
| Fagaras | 176 | Sibiu | 253 |
| Giurgiu | 77 | Timisoara | 329 |
| Hirsova | 151 | Urziceni | 80 |
| Iasi | 226 | Vaslui | 199 |
| Lugoj | 244 | Zerind | 374 |

## Best-first search

Idea: use an evaluation function for each node

- estimate of "desirability"
$\Rightarrow$ Expand most desirable unexpanded node
Implementation:
fringe is a queue sorted in decreasing order of desirability
Special cases:
greedy search
A* search

## Greedy search

Evaluation function $h(n)$ (heuristic)
$=$ estimate of cost from $n$ to the closest goal
E.g., $h_{\mathrm{SLD}}(n)=$ straight-line distance from $n$ to Bucharest

Greedy search expands the node that appears to be closest to goal prefer the action that takes us to the state with the minimum heuristic cost.

Time?? $O\left(b^{m}\right)$, but a good heuristic can give dramatic improvement
Space?? $O\left(b^{m}\right)$-keeps all nodes in memory
Optimal?? No

Alan Smaill

## A* search

A* search has a very good property:
$A^{*}$ search is optimal!
So if there is any solution, $A^{*}$ search is guaranteed to find a least cost solution. Remember, this needs an admissible heuristic.

## A* search

Idea: avoid expanding paths that are already expensive
Evaluation function $f(n)=g(n)+h(n)$
$g(n)=$ cost so far to reach $n$
$h(n)=$ estimated cost to goal from $n$
$f(n)=$ estimated total cost of path through $n$ to goal
A* search uses an admissible heuristic, i.e.

$$
h(n) \leq h^{*}(n)
$$

where $h^{*}(n)$ is the true cost of cheapest solution from $n$. (Also require $h(n) \geq 0$, so $h(G)=0$ for any goal $G$.)
E.g., $h_{\text {SLD }}(n)$ never overestimates the actual road distance.

## Optimality of $\mathbf{A}^{*}$ (more useful)

Lemma: A* expands nodes in order of increasing $f$ value
Gradually adds " $f$-contours" of nodes (cf. breadth-first adds layers)
Contour $i$ has all nodes with $f=f_{i}$, where $f_{i}<f_{i+1}$

## Optimality of $\mathbf{A}^{*}$ (standard proof)

Suppose some suboptimal goal $G_{2}$ has been generated and is in the queue. Let $n$ be an unexpanded node on a shortest path to an optimal goal $G_{1}$.

Then:

$$
f\left(G_{2}\right)=g\left(G_{2}\right) \text { since } h\left(G_{2}\right)=0
$$

$>g\left(G_{1}\right)$ since $G_{2}$ is suboptimal
$\geq f(n)$ since $h$ is admissible
Since $f\left(G_{2}\right)>f(n)$, $\mathrm{A}^{*}$ will never select $G_{2}$ for expansion.

Alan Smaill
Fundamentals of Artificial Intelligence
Oct 8, 2007

## Properties of $\mathbf{A}^{*}$

Complete?? Yes, unless there are infinitely many nodes with $f \leq f(G)$
Time??

## Properties of $\mathbf{A}^{*}$

Complete?? Yes, unless there are infinitely many nodes with $f \leq f(G)$
Time?? Exponential in [relative error in $h \times$ length of soln.]
Space??

## Admissible heuristics

E.g., for the 8-puzzle:
$h_{1}(n)=$ number of misplaced tiles
$h_{2}(n)=$ total Manhattan distance
(i.e., no. of squares from desired location of each tile)

$$
\begin{aligned}
& h_{1}(S)=? ? \\
& h_{2}(S)=? ?
\end{aligned}
$$

## Properties of $\mathbf{A}^{*}$

Complete?? Yes, unless there are infinitely many nodes with $f \leq f(G)$
Time?? Exponential in [relative error in $h \times$ length of soln.]
Space?? Keeps all nodes in memory
Optimal?? Yes—cannot expand $f_{i+1}$ until $f_{i}$ is finished
A* expands all nodes with $f(n)<C^{*}$
A* expands some nodes with $f(n)=C^{*}$
A* expands no nodes with $f(n)>C^{*}$
$\overline{\text { Alan Smaill }}$
Fundamentals of Artificial Intelligence

## Admissible heuristics

E.g., for the 8-puzzle:
$h_{1}(n)=$ number of misplaced tiles
$h_{2}(n)=$ total Manhattan distance
(i.e., no. of squares from desired location of each tile)

$h_{1}(S)=$ ?? 6
$h_{2}(S)=? ? \quad 4+0+3+3+1+0+2+1=14$

## Dominance

If $h_{2}(n) \geq h_{1}(n)$ for all $n$ (both admissible)
then $h_{2}$ dominates $h_{1}$ and is better for search
Typical search costs for solution at length $d$ :

$$
\begin{array}{ll}
d=14 & \text { IDS }=3,473,941 \text { nodes } \\
& \mathrm{A}^{*}\left(h_{1}\right)=539 \text { nodes } \\
& \mathrm{A}^{*}\left(h_{2}\right)=113 \text { nodes } \\
d=24 & \text { IDS } \approx 54,000,000,000 \text { nodes } \\
& \mathrm{A}^{*}\left(h_{1}\right)=39,135 \text { nodes } \\
& \mathrm{A}^{*}\left(h_{2}\right)=1,641 \text { nodes }
\end{array}
$$

Admissible heuristics can be derived from the exact
solution cost of a relaxed version of the problem
If the rules of the 8 -puzzle are relaxed so that a tile can move anywhere, then $h_{1}(n)$ gives the shortest solution
If the rules are relaxed so that a tile can move to any adjacent square, then $h_{2}(n)$ gives the shortest solution
Key point: the optimal solution cost of a relaxed problem is no greater than the optimal solution cost of the real problem

## ${ }_{35}$ informatics

## Summary

Work with an evaluation function for each node

- Greedy search algorithms - go for most desirable node
- $A^{*}$ search using an admissible heuristic function
- $A^{*}$ is optimal search strategy
- Heuristics for the eight puzzle
