Problems Left Recursion Ambiguity

Summary

Review CFGs

- Sets of terminals (either lexical items or parts of speech).
- Sets of non-terminals (the constituents of the language).
- Sets of rules (or 'productions') of the form $A \rightarrow \alpha$, where α is a string of zero or more terminals and non-terminals.

DERIVES:

- ▶ If grammar *G* contains the rule $A \rightarrow \gamma$ and $\alpha A\beta$ is a string in $(N \cup \Sigma)^*$, then $\alpha A\beta$ DIRECTLY DERIVES $\alpha \gamma\beta$ in *G*: $\alpha A\beta \Rightarrow \alpha \gamma\beta$.
- ► $\stackrel{*}{\Rightarrow}$ (DERIVES) is the reflexive, transitive closure of \Rightarrow ; e.g., S $\stackrel{*}{\Rightarrow} \alpha$ if S $\stackrel{*}{\Rightarrow} \alpha_0$, $\alpha_0 \stackrel{*}{\Rightarrow} \alpha_1$, ..., $\alpha_n \stackrel{*}{\Rightarrow} \alpha$.

(4 同) (4 回) (4 \Pi) (4 \Pi)

Parsing

Assign a correct tree to a string, given a grammar G, i.e.,

- The leaves of the tree cover all and only the input.
- ▶ The tree corresponds to a valid derivation according to *G*.
- 'correct':
 - means the tree is consistent with the input and the grammar;
 - doesn't mean that it's the proper way to represent English in any general sense.

Declarative vs./ Procedural Knowledge

- CFGs are declarative: they tell us what the well-formed structures and strings are.
- Parsers are procedural: they tell us how to compute the structure(s) for a given string.

< ∃ >

Parsing as Search

Syntactic parsing can be viewed as a search (cf. Jurafsky & Martin):

- search space: all possible trees generated by the grammar;
- search space defined by the grammar;
- search guided by the structure of the space and the input.

Mini Grammar & Lexicon

$S \rightarrow NP VP \mid Aux NP VP \mid VP$	Det \rightarrow <i>that</i> <i>this</i> <i>a</i>
$NP \rightarrow Det Nom PropN$	$N \to book \mid flight \mid meal$
$Nom \to Nom PP \mid N Nom$	$V \rightarrow book \mid include \mid prefer$
$PP \to P NP$	$Aux \rightarrow does$
$VP \rightarrow V \mid V NP$	$P \to \mathit{from} \mid \mathit{to} \mid \mathit{on}$
$Nom \to N PP \mid N Nom$	$PropN \to \mathit{Houston} \mid \mathit{TWA}$

э

Top-Down Bottom-Up

Parsing

What kind of constraints can be used to connect the grammar and our example sentence when searching for the parse tree?

- top-down (goal-directed) strategy:
 - e.g., tree should have one root (grammar constraint)
- bottom-up (data-driven) strategy:
 - e.g., tree should have 3 leaves (input sentence constraint)

A B > A B >

Top-Down Bottom-Up

A Note on the Input

We assume the following:

- The input is not tagged.
- The input consists of unanalyzed word tokens.
- e words in the input are 'known' (i.e., are leaves of lexical rules in grammar).
- All the words in the input are available simultaneously (i.e., they're buffered).

Top-Down Bottom-Up

Top-Down Parsing

- When the search is primarily goal- or expectation-driven (by the structure of the grammar), we're doing a top-down search.
- Primary goal is to find a tree rooted at S that derives the input string.
- Trees are built from the root node S to the leaves.

>>> from nltk_lite.draw.rdparser import demo
>>> demo()

I ≡ ▶ < </p>

Top-Down Bottom-Up

Bottom-Up Parsing

- When the search is primarily data-driven (by the input string), we're doing a BOTTOM-UP search.
- The primary consideration here is that all of the sub-trees of the final tree must hook up with the start symbol.
- NLTK-Lite demo of Shift-Reduce parser

>>> from nltk_lite.draw.srparser import demo
>>> demo()

Top-Down Bottom-Up

Search Control Issues

Some parameters still need to be made explicit:

- non-parallel strategies (e.g., depth-first vs. breadth-first);
- which node in the tree to expand next (e.g., leftmost);
- which of the applicable grammar rule to try (e.g., order in the grammar)

Top-Down Bottom-Up

Top-Down vs. Bottom-Up

There are advantages and disadvantages to both. TOP-DOWN:

- only searches in the space of 'reasonable' answers;
- suggests hypotheses that are not consistent with the input string;
- ▶ has problems with left-recursion (covered later).

BOTTOM-UP

- only forms hypotheses consistent with the input strings;
- suggests hypotheses that make no sense 'globally'.

★ ∃ →

A Hybrid Approach

- Neither top-down nor bottom-up adequately exploit all the constraints.
- There are many way to combine top-down expectations with bottom-up data to get a more efficient search.
- The most popular methods use one method as the basic search control strategy to generate trees, and
- then use constraints from the other method to dynamically filter out "bad" structures.
- Example: top-down parsing with bottom-up filtering.

Left Corner Parsing

 Consider a top-down parser parsing the following input: Will this flight arrive on time? Assume that the grammar contains the following S rules:

$$\begin{array}{l} S \rightarrow NP \quad VP \\ S \rightarrow Aux \quad NP \quad VP \\ S \rightarrow VP \end{array}$$

Left-Corner Observation: in a successful parse, the current input word is first in the derivation of the unexpanded node.

Left Corners

- A category B (terminal or non-terminal) is a LEFT CORNER of a tree rooted in A if A derives Bα.
- Left corners for each non-terminal in our mini-grammar:

Category	Left Corners
S	Det, Proper-Noun, Aux, V
NP	Det, Proper-Noun
Nom	Ν
VP	V

< ∃ >

P.

∃ >

- ▶ V and *prefer* are both left-corners of the tree rooted in VP.
- Filtering with left corners:
 - Only consider an expansion if current input can serve as the left-corner of that expansion.

Left Recursion Ambiguity

Left Recursion

In top-down, depth-first, left-to-right parsers, a left recursive grammar can cause the search to never terminate.

$$A \rightarrow A\beta$$

$$Nom \rightarrow Nom PP$$

$$VP \rightarrow VP PP$$

$$S \rightarrow S and S$$

 A derives Aβ (i.e., the grammar contains a non-terminal that contains itself anywhere along its leftmost branch)

$$NP \rightarrow NP_{poss}$$
 Nom $NP_{poss} \rightarrow NP$'s

Left Recursion Ambiguity

Left Recursion, cont.

- Demo example: Nom \rightarrow Nom PP
- Some (poor) solutions:
 - Rewrite the grammar to a weakly equivalent one (how?)
 - might not get a correct or useful parse tree.
 - Limit the depth during search
 - limit is arbitrary.

∃ >

Left Recursion Ambiguity

Ambiguity

Given a grammar, GLOBAL AMBIGUITY potentially leads to multiple parses for the same input (if we force it to).

I saw a woman with a telescope.

LOCAL AMBIGUITY, in contrast, leads to hypotheses that are locally reasonable but eventually lead nowhere and result in inefficient backtracking. Filtering helps a little.

Book that flight.

-

Left Recursion Ambiguity

Why is Ambiguity Problematic?

- There are potentially an exponential number of parses for a sentence.
 - Returning all structurally valid parses isn't always a good idea.
- Some solutions:
 - exploit regularities in the search space to derive common subparts only once;
 - heuristic search strategies;
 - incorporate semantics into the disambiguation process.
