

These notes are intended to give a summary of relevant concepts from the lectures which are helpful to complete the exercises. It is not intended to cover the lectures thoroughly. Learning this content is not a replacement for working through the lecture material and the exercises.

Note the difference between the notations $p(\mathbf{x}; \boldsymbol{\theta})$ and $p(\mathbf{x} \mid \boldsymbol{\theta})$. The former is a pdf/pmf of a random variable \mathbf{x} that is parametrised by a vector of numbers (parameters) $\boldsymbol{\theta}$. The latter is a *conditional* pdf/pmf of a random variable \mathbf{x} given information of another *random variable* $\boldsymbol{\theta}$.

Likelihood $L(\theta)$ — The chance that the model generates data like the observed one when using parameter configuration θ . For *iid* data $\mathcal{D} = \{\mathbf{x}_1, \ldots, \mathbf{x}_n\}$, the likelihood of the parameters θ is

$$L(\boldsymbol{\theta}) = p(\mathcal{D}; \boldsymbol{\theta}) = \prod_{i=1}^{n} p(\mathbf{x}_i; \boldsymbol{\theta})$$
(1)

Prior $p(\theta)$ — Beliefs about the plausibility of parameter values before we see any data.

Posterior $p(\boldsymbol{\theta} \mid \mathcal{D})$ — Beliefs about the parameters after having seen the data. This is proportional to the likelihood function $L(\boldsymbol{\theta})$ weighted by our prior beliefs about the parameters $p(\boldsymbol{\theta})$

$$p(\boldsymbol{\theta} \mid \mathcal{D}) \propto L(\boldsymbol{\theta})p(\boldsymbol{\theta}) \tag{2}$$

Parametric statistical model — A set of pdfs/pmfs indexed by parameters θ ,

$$\{p(\mathbf{x};\boldsymbol{\theta})\}_{\boldsymbol{\theta}}\tag{3}$$

• Parameter estimation Using \mathcal{D} to pick the "best" parameter value $\hat{\boldsymbol{\theta}}$ among the possible $\boldsymbol{\theta}$ – i.e. pick the "best" pdf/pmf $p(\mathbf{x}; \hat{\boldsymbol{\theta}})$ from the set of pdfs/pmfs $\{p(\mathbf{x}; \boldsymbol{\theta})\}_{\boldsymbol{\theta}}$,

Bayesian model — Considers $p(\mathbf{x}; \boldsymbol{\theta})$ to be conditional $p(\mathbf{x} \mid \boldsymbol{\theta})$. Models the distribution of the parameters $\boldsymbol{\theta}$, as well as the random variable \mathbf{x}

$$p(\mathbf{x}, \boldsymbol{\theta}) = p(\mathbf{x} \mid \boldsymbol{\theta}) p(\boldsymbol{\theta}) \tag{4}$$

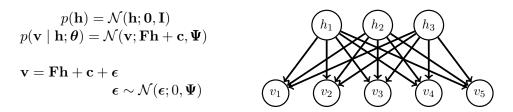

• Bayesian inference Determine the plausibility of all possible θ in light of the observed data – i.e. compute the posterior $p(\theta \mid D)$.

Maximum likelihood — The parameters $\hat{\theta}$ that give the largest likelihood (or log-likelihood)

$$\hat{\boldsymbol{\theta}} = \operatorname*{argmax}_{\boldsymbol{\theta}} \ell(\boldsymbol{\theta}) = \operatorname*{argmax}_{\boldsymbol{\theta}} L(\boldsymbol{\theta})$$
(5)

Sometimes this can be computed directly (as in the tutorials). However, numerical methods are often needed for this optimisation problem, which leads to local optima.

Factor analysis — A graphical model where statistical dependencies between the observed variables (visibles \mathbf{v}) is modelled through unobserved variables (latents \mathbf{h}). In factor analysis, the latents \mathbf{h} are assumed to be independent Gaussians with zero mean and unit variance.

The covariance matrix Ψ is a diagonal matrix. Probabilistic PCA is a special case of factor analysis, where $\Psi = \sigma^2 \mathbf{I}$.

Independent component analysis — The DAG is the same as in factor analysis, but with non-Gaussian latents (one latent may be Gaussian)

$$p(\mathbf{h}) = \prod_{i} p(h_i)$$
$$p(\mathbf{v} \mid \mathbf{h}; \boldsymbol{\theta}) = \mathcal{N}(\mathbf{v}; \mathbf{A}\mathbf{h} + \mathbf{c}, \boldsymbol{\Psi})$$
