Software Design

- **Software Design:** the **process** of defining the **architecture, components, interfaces** and other **characteristics** of a system or component. [IEEE standard glossary]
 - The Link to **Requirements**
 - Key Design **techniques** and **issues**
 - **Structure** and **architecture**
 - the main elements of software that need to be managed
 - design in the large and design in the small
 - Design notations
 - Design quality and evaluation
- **Design:** 1. The process of defining the software architecture, components, modules, interfaces, and data for a software system to satisfy specified requirements. 2. The results of the design process. [IEEE Software]
- **Software Design:** The use of scientific **principles**, technical information, and imagination in the definition of a software system to perform prespecified **functions** with maximum **economy** and **efficiency**. [IEEE Software]
 - Design is a pervasive activity
 - often there is no definitive solution
 - solutions are highly context dependent
 - No "magic bullet" in general

The Link to Requirements

- Design links requirements to “implementable specifications”
- **Traceability** - retaining the link from requirements to components
 - By **allocating** a particular **requirement** to a particular **component** as we decompose, e.g., in VolBank, we might require a log
 - By **decomposing** requirements into more refined requirements on particular components, e.g., a particular function in VolBank might be realized across several components
 - Some requirements (e.g., usability) are harder to decompose, e.g., it takes 30 minutes to become competent in using the system
- We might require traceability back from the design

Traceability

- There are four basic types of traceability:
 - **Pre-traceability** (e.g., requirements-sources, requirements-rationale, etc.)
 1. **Forward-to** requirements traceability links other documents preceding requirements (e.g., users document)
 2. **Backward-from** requirements traceability links requirements to their sources (e.g., rationale)
 - **Post-traceability** (e.g., requirements-architecture, requirements-design, requirements-interface, etc.)
 3. **Forward-from** requirements traceability links requirements to design and implementation
 4. **Backward-to** requirements traceability links design and implementation back to requirements.
- To manage requirements, you need to maintain traceability information (e.g., Traceability Tables)
 - Requirements Management Tools support traceability practice (e.g., IBM Rational RequisitePro or Telelogic DOORS)

Key Design Techniques

- **Abstraction**
 - ignoring detail to get the high level structure right
- **Decomposition and Modularization**
 - big systems are composed from small components
- **Encapsulation/information hiding**
 - the ability to hide detail (linked to abstraction)
- **Defined interfaces**
 - separable from implementation
- **Evaluation of structure:**
 - **Coupling**: How interlinked a component is
 - **Cohesion**: How coherent a component is

Key Issues in Software Design

■ Concurrency

- Often there is significant interaction that needs management
- What are the main concurrent activities?
- How do we manage their interaction?
- **VolBank**: matching and specifying skills and needs goes on concurrently

■ Workflow and event handling

- What are the activities inside a workflow?
- How do we handle events?

■ Distribution

- How is the system distributed over physical (and virtual) systems?

■ Error handling and recovery

- Action when a physical component fails (e.g., the database server)
- How to handle exceptional circumstances in the world
- **VolBank**: a volunteer fails to appear

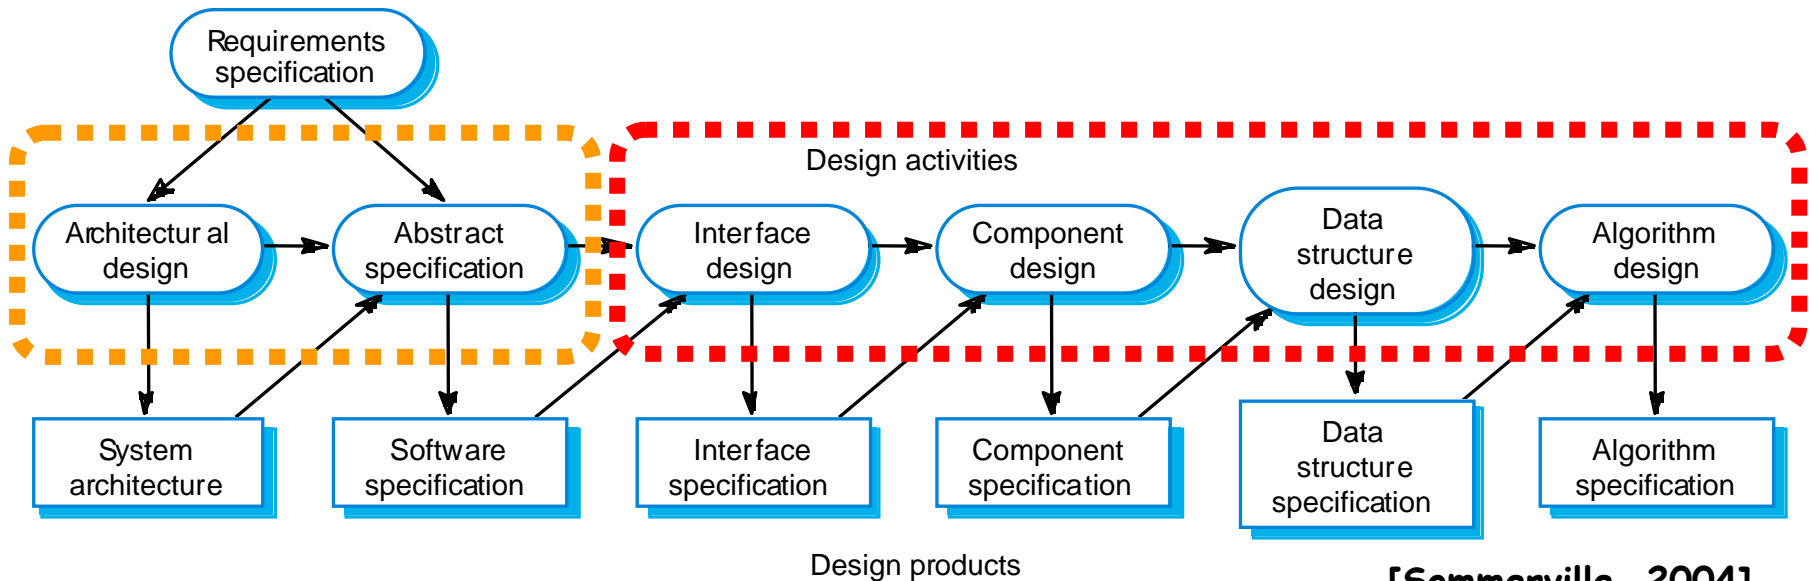

■ Persistence of data:

- Does data need to persist across uses of the system, how complex?
- How much of the state of the process?

■ Can you think through some of these issues for **VolBank**?

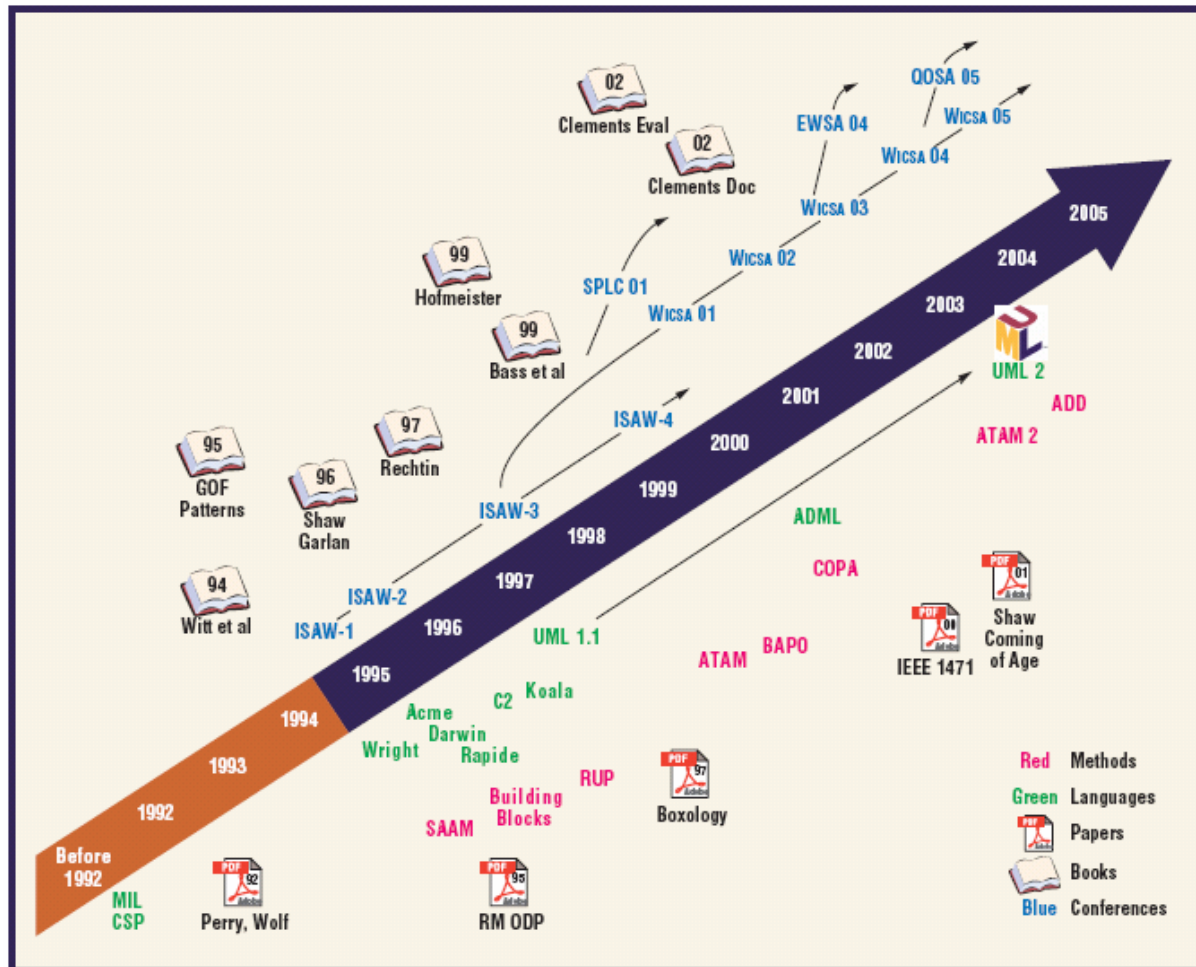

A Design Process

- Main activity in design:
 - decomposing system (**components**) into smaller more manageable components
 - definitions of components that are easily codable
- Usually a two stage process: **Architectural Design** and **Detailed Design**
 - **Architectural Design** (or High-level Design)
 - What are the components and how do they relate?
 - How does the system architecture deal with issues that pervade the system?
 - **Detailed Design** deals with the function and characteristics of components and how they relate to the overall architecture.

Architectural Design and UML

[Kruchten, Obbink, Stafford 2006]

Architecture and Structure

- **Architectural structures and viewpoints**
 - attempt to deal with facets separately, e.g., physical view, functional (or logical) view, security view, etc.
- **Architectural styles**, for example:
 - Three-tier architecture for a distributed system (interface, middleware, back-end database)
 - Blackboard
 - Layered architectures
 - Model-View-Controller
 - Time-triggered
- **Design patterns**
 - small-scale patterns to guide the designer
- **Families and frameworks**
 - component set and ways of plugging together
 - software product lines

Architectural Design

■ Advantages:

- Stakeholder Communication
- System Analysis
- Large-scale reuse

■ Design Strategies

- **Function Oriented:** sees the design of the functions as primary
 - **Data Oriented:** sees the data as the primary structured element and drives design from there
 - **Object Oriented:** sees objects as the primary element of design
- There is no clear distinction between Sub-systems and modules. Intuitively,
- Sub-systems are independent and composed of modules, have defined interfaces for communication with other sub-systems
 - Modules are system components and provide/make use of service(s) to/provided by other modules

Architecture Models

- Architecture Models that may be developed may include:
 1. A **static structural model** that shows the sub-systems or components that are to be developed as separate units.
 2. A **dynamic process model** that shows how the system is organized into processes at run-time. This may be different from the static model.
 3. An **interface model** that defines the services offered by each sub-system through their public interface.
 4. A **relationship model** that shows relationships such as data flow between the sub-systems.

Quality Analysis and Evaluation

- The system architecture affects the quality attributes of a system
- **Quality attributes:**
 - Performance, security, availability,... modifiability, portability, reusability, testability, maintainability, etc.
- **Quality analysis:**
 - reviewing techniques, static analysis, simulation, performance analysis, prototyping
- **Measures (metrics):**
 - Defined measure on the design
 - Predictive, but usually very dependent on the process in use

Architectural Design: Key Points

- The software **architecture** is the fundamental framework for **structuring the system**
- Different **architectural models** (e.g., system organizational models, modular decomposition models and control models) may be developed
- Design decisions enhance **system attributes**
 - **Performance**, e.g., localize operations to minimize sub-system communication
 - **Security**, e.g., use a layered architecture with critical assets in inner layers
 - **Safety**, e.g., isolate safety-critical components
 - **Availability**, e.g., include redundant components in the architecture
 - **Maintainability**, e.g., use fine-grain self-contained components

What are the Architect's Duties?

- Get it **Defined, documented and communicated**
 - Act as the emissary of the architecture
 - Maintain morale
- Make sure
 - everyone is **using** it (correctly)
 - management understands it
 - the **software** and system **architectures** are in synchronization
 - the right **modeling** is being done, to know that **quality attributes** are going to be met
 - the architecture is not only the right one for **operations**, but also for **deployment** and **maintenance**
- Identify
 - architecture timely **stages** that support the overall organization progress
 - suitable **tools** and **design** environments
 - (and interact) with **stakeholders**
- Resolve
 - disputes and make tradeoffs
 - technical problems
- Manage **risk** identification and risk **mitigation strategies** associated with the architecture
 - understand and plan for **evolution**

VolBank: Example

- Suppose we consider two requirements:
 - That a request for a volunteer should produce a list of volunteers with appropriate skills.
 - The system shall ensure the safety of both volunteers and the people and organizations who host volunteers.
 - This may decompose into many more specific requirements:
 - That the organization has made reasonable efforts to ensure a volunteer is bona fide.
 - » That we have a confirmed address for the individual: i.e., the original address is correct, and only the volunteer can effect a change in address.

Summary

- Design is a complex matter
- Design links requirements to construction, essential to ensure traceability
- Generally two stages:
 - Architecture Design (or High-level Design)
 - Detailed Design
- Many notations and procedures to support design
- More domain-specificity for easier design task
