

Secure Programming Lecture 9: Web Application Security (intro, authentication)

David Aspinall

15th February 2018

Outline

Introduction

Basics: HTTP

Authentication

Cookies and sessions

Summary

OWASP

The **Open Web Application Security Project** is a charity started in 2001, to promote mechanisms for securing web apps in a non-proprietary way.

They have local chapters worldwide; the **Scotland chapter** sometimes meets in Appleton Tower.

Like **CERT** and **Mitre**, OWASP produce taxonomies of weaknesses and coding guidelines.

Their most well known output is the **OWASP Top 10** list of weaknesses in web applications.

OWASP Top 10 list 2017

OWASP Top 10 - 2017

The Ten Most Critical Web Application Security Risks

OWASP Top 10 list 2017

- ▶ A1 Injection
- ▶ A2 Broken Authentication
- ▶ A3 Sensitive Data Exposure
- ▶ A4 XML External Entities (XXE)
- ▶ A5 Broken Access Control
- ▶ A6 Security Misconfiguration
- ▶ A7 Cross-Site Scripting (XSS)
- ▶ A8 Insecure Deserialization
- ▶ A9 Using Components with Known Vulnerabilities
- ▶ A10 Insufficient Logging & Monitoring

The list is compiled using surveys of application security companies and an industry survey of 500 people, claiming to represent over 100k apps/APIs.

See https://www.owasp.org/index.php/Top_10-2017_Top_10

Changes since OWASP Top 10 list 2013

Web app programming changes:

- ▶ Growth of **microservices**, using APIs and REST
 - ▶ architectural assumptions on old code violated
- ▶ **Single Page Apps** (Angular, React)
 - ▶ functionality moved from server to client

Top 10 changes suggested by data and community:

- ▶ XML handling, deserialisation
- ▶ Logging

Moved down in priority: CSRF, unvalidated redirects.

Roadmap

- ▶ A1 Injection ✓
- ▶ A2 **Broken Authentication**
- ▶ ...

In the next few lectures and lab sessions we'll look at web app security and some of the main weakness categories.

Overview

We start with a quick review of the basics.

Whether you program web sites using a

- ▶ Microservice architecture (*Node.js, Spring Boot*)
- ▶ Web Application Framework (*Rails, Django, ...*)
- ▶ Content Management System (*Joomla, Drupal, ...*)
- ▶ Wiki (*MediaWiki, Confluence, ...*)
- ▶ Blog (*Wordpress, ...*)
- ▶ ... anything else

knowing what is happening underneath is important to understand how security provisions work (or don't).

Similarly, we looked at assembler code and CPU execution for C applications, to understand what was *really* going on “under the bonnet”.

Outline

Introduction

Basics: HTTP

Authentication

Cookies and sessions

Summary

HTTP

HTTP = Hyper Text Transfer Protocol

- ▶ Protocol used for web browsing
 - ▶ and many other things by now (Q. Why?)
- ▶ Specifies messages exchanged
 - ▶ HTTP/1.1 specified in RFC 2616
 - ▶ request methods: GET, POST, PUT, DELETE
- ▶ Messages are text based, in lines (Unix: CR+LF)
- ▶ *Stateless* client-side design
 - ▶ quickly became a problem, hence **cookies**
- ▶ NB: HTTP is entirely separate from HTML!
 - ▶ HTTP headers not HTML <HEAD>
 - ▶ HTML is text format for web *content*

HTTP communication

HTTP is a client-server protocol.

- ▶ Client initiates TCP connection (usually port 80)
- ▶ Client sends HTTP request over connection
- ▶ Server responds
 - ▶ may close connection (HTTP 1.0 default)
 - ▶ or keep it *persistent* for a wee while
- ▶ Server never initiates a connection
 - ▶ except in newer **HTML5 WebSockets**
 - ▶ WebSockets allow low-latency interactivity
 - ▶ Upgrade: websocket handshake & switch to WS
 - ▶ expect to see rise in use and security issues. . .

HTTP GET message (simplified)

GET / HTTP/1.1

Host: www.bbc.co.uk

User-Agent: Mozilla/5.0

Accept: text/html

Accept-Language: en-US,en;q=0.5

HTTP GET message (full)

GET / HTTP/1.1

Host: www.bbc.co.uk

User-Agent: Mozilla/5.0 (Macintosh; Intel Mac OS X 10.9; rv:27.0) Gecko

Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.

Accept-Language: en-US,en;q=0.5

Accept-Encoding: gzip, deflate

DNT: 1

Connection: keep-alive

Pragma: no-cache

Cache-Control: no-cache

HTTP Response (simplified)

```
HTTP/1.1 200 OK
Server: Apache
Content-Type: text/html; charset=UTF-8
Date: Wed, 19 Feb 2014 14:30:42 GMT
Connection: keep-alive
```

```
<!DOCTYPE html> <html lang="en-GB" > <head> <!-- Barlesque 2.60.1 -->
<meta http-equiv="Content-Type" content="text/html; charset=UTF-8" />
<meta name="description" content="Explore the BBC, for latest news,
sport and weather, TV & radio schedules and highlights, with
nature, food, comedy, children's programmes and much more" />
...
```

HTTP Response (full)

```
HTTP/1.1 200 OK
Server: Apache
Etag: "c8f621dd5455eb03a12b0ad413ab566f"
Content-Type: text/html
Transfer-Encoding: chunked
Date: Wed, 19 Feb 2014 20:12:34 GMT
Connection: keep-alive
Set-Cookie: BBC-UID=a583d...4929Mozilla/5.0; expires=Sun, 19-Feb-18 20
X-Cache-Action: HIT
X-Cache-Hits: 574
X-Cache-Age: 50
Cache-Control: private, max-age=0, must-revalidate
X-LB-NoCache: true
Vary: X-CDN

d1c
<!DOCTYPE html>
...
```

Note: cache fingerprint; chunked transfer; **cookie**; cache directives.

Client != Browser

```
[dice]da: telnet www.bbc.co.uk 80
Trying 212.58.244.71...
Connected to www.bbc.net.uk.
Escape character is '^]'.
GET / HTTP/1.0
Host: www.bbc.co.uk
Accept: text/html, text/plain, image/*
Accept-Language: en
User-Agent: Handwritten in my terminal
```

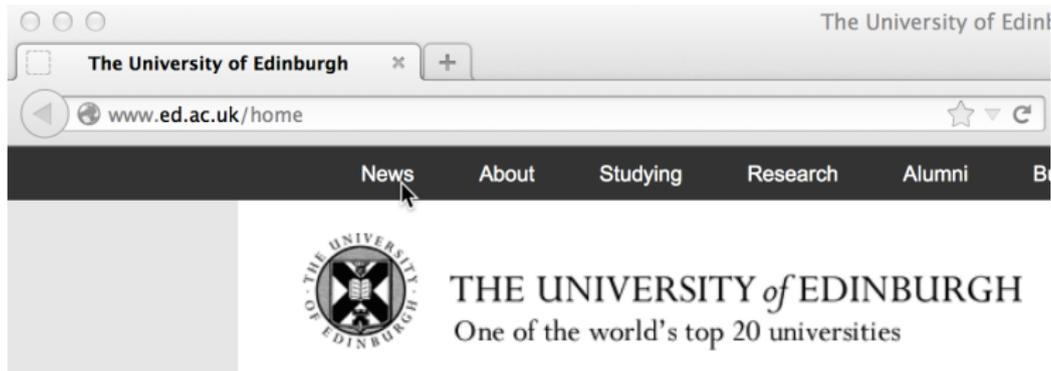

Client != Browser

```
HTTP/1.1 200 OK
Server: Apache
Content-Type: text/html
Date: Wed, 19 Feb 2014 14:26:00 GMT
...
```

Client-side security doesn't exist

- ▶ Any program can conduct HTTP(S) communications
- ▶ ... URLs can be constructed arbitrarily
- ▶ ... POST forms content also
- ▶ In server-side context, there are *no input validation guarantees* despite any client-side code.

Referer header

GET /news/ HTTP/1.1

Host: www.ed.ac.uk

User-Agent: Mozilla/5.0 (Macintosh; Intel Mac OS X 10.9; rv:27.0) Gecko

Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.

Accept-Language: en-US,en;q=0.5

Accept-Encoding: gzip, deflate

DNT: 1

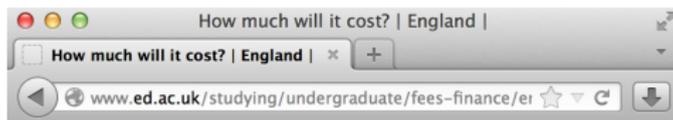

Referer: http://www.ed.ac.uk/home

Connection: keep-alive

Referer header

Question. What immediate security issue arises from this header?

Referer header

RUK

» Rest of the UK (England, Wales and Northern Ireland)

Students who normally live in England will have a fee status of Home-RUK.

If you are studying full-time for your first degree, you may be eligible to apply for a tuition fee loan to cover your tuition fees in full.

You make one application to Student Finance England, for your fee loan and your student support. The Student Loans Company (SLC) will pay your tuition fees to the University.

The £9,000 tuition fee is applicable for all full-time undergraduate degree programmes except for graduate entry to the BVM&S Veterinary Medicine and graduate entry to the LLB Law programmes.

We are awaiting confirmation that applicants to the BN Nursing Studies can apply to the Student Awards Agency Scotland to have their tuition fees paid on their behalf.

If you are in any doubt regarding your eligibility for support, please contact Student Finance England.

> [Tell me more about tuition fees](#)

> [Student Finance England](#)

> [Student Awards Agency](#) outgoing link

How your tuition fees will be paid

If you have a confirmed award which covers your tuition fee you will not be invoiced for fees.

www.sfengland.slc.co.uk

Referer header

```
GET /loggedin/secretfile.html HTTP/1.1
Host: www.mycompany.com
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.5
Accept-Language: en-US,en;q=0.5
Accept-Encoding: gzip, deflate
DNT: 1
Referer: http://www.mycompany.com/loggedin/
```

Don't rely on Referer header for access decisions!

- ▶ Flawed assumption made in old web apps:
user has navigated to a logged in area, therefore they must be logged in
- ▶ But Referer is from client, cannot be trusted!
- ▶ Also risky because of TOCTOU
- ▶ and confuses authentication with authorization

Inputs via GET Request

`http://www.shop.com/products.asp?name=Dining+Chair&material=Wood`

- ▶ Input encoded into *parameters* in URL
- ▶ Bad for several reasons:
 - ▶ SEO optimisation: URL not canonical
 - ▶ cache behaviour (although not relevant for login)

Question. What's another reason this format is bad?

Inputs via GET Request

`http://someplace.com/login.php?username=jdoe&password=BritneySpears`

- ▶ URL above is visible in browser navigation bar!

POST Request

```
POST /login.php HTTP/1.0  
Host: www.someplace.example  
Pragma: no-cache
```

```
Cache-Control: no-cache  
User-Agent: Mozilla/5.0 (X11; U; Linux i686; en-US; rv:1.5a)  
Referer: http://www.someplace.example/login.php  
Content-type: application/x-www-form-urlencoded  
Content-length: 49
```

```
username=jdoe&password=BritneySpears
```

- ▶ URL in browser:
`http://www.someplace.example/login.php`

GET versus POST

- ▶ **GET** is a *request* for information
 - ▶ can be (transparently) resent by browsers
 - ▶ also may be cached, bookmarked, kept in history
- ▶ **POST** is an *update* providing information
 - ▶ gives impression that input is hidden
 - ▶ browsers may treat differently
- ▶ **neither provide confidentiality** without HTTPS!
 - ▶ plain text, can be sniffed
- ▶ in practice, GET often changes state somewhere
 - ▶ user searches for something, gets recorded
 - ▶ user has navigated somewhere, gets recorded
 - ▶ so shouldn't think GET implies functional

When to use POST instead of GET

- ▶ For sensitive data, *always* use POST
 - ▶ helps with confidentiality but not enough alone
- ▶ For large data, use POST
 - ▶ URLs should be short (e.g., ≤ 2000 chars)
 - ▶ longer URLs cause problems in some software
- ▶ For actions with (major) side effects use POST
 - ▶ mainly correctness; many early web apps wrong

These are general guidelines. There are sometimes more complex technical issues to prefer GET.

Outline

Introduction

Basics: HTTP

Authentication

Cookies and sessions

Summary

Authentication

You know this already:

- ▶ Something you have
- ▶ Something you know
- ▶ Something you are

Question. What else?

Question. What about machine-machine authentication?

Is the application vulnerable?

- ▶ Credentials can be guessed or overwritten through weak account management functions
 - ▶ default passwords
 - ▶ broken account creation/recovery
- ▶ Automated brute-force attacks possible (“credential stuffing”)
- ▶ Passwords or other credentials are sent over unencrypted connections.
- ▶ Credentials aren’t protected when stored (stolen entries vulnerable to offline attack)
- ▶ Multi-factor (or recovery factor) broken/missing

Exercise. Explain/revise how each of these drawbacks can be addressed.

Modern password recommendations

- ▶ Avoid passwords if possible
- ▶ Don't require rotation unless compromise signs
- ▶ Recommend secure storage mechanisms
- ▶ Check for weak passwords, use (sane) password complexity rules
- ▶ Rate-limit logins to prevent automated attacks
- ▶ Use **multi-factor authentication** for recovery

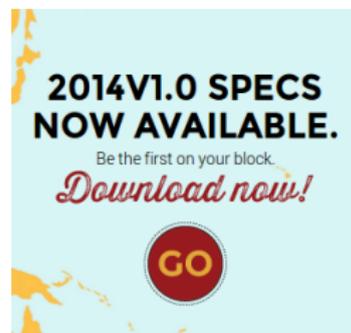

An example where recent practical academic research has had some nice impact. See

- ▶ the 2016 UK NCSC [Password guidance: simplifying your approach](#)
- ▶ the 2017 [NIST 800-63B](#) which has a comprehensive proposal for *Authentication Assurance Levels*

Outlook for web authentication/identity

We're likely to see more shared facilities (and a battle):

- ▶ Interoperable schemes, e.g. **OWASP ASVS**
- ▶ Perhaps using OAUTH, OpenID
- ▶ **FIDO**, an industry-led initiative to replace passwords

- ▶ Maybe Government identity verification, e.g., **GOV.UK Verify**.

Outline

Introduction

Basics: HTTP

Authentication

Cookies and sessions

Summary

Cookies: state in a stateless world

Some state is highly desirable between requests:

- ▶ remember user's preferences, navigation point, ...
- ▶ web applications: **user logged in**

However, also the less desirable:

- ▶ advertising network **tracking ids**
- ▶ may be shared between websites
- ▶ thus can profile user browsing behaviour
- ▶ hence **compromise privacy**
- ▶ also **risk of theft**
 - ▶ if browser/machine compromised, or
 - ▶ if cookies passed in clear

Cookies and the law

See Sitebeam's cheeky infographic

Cookies in HTTP headers

- ▶ Specified in **RFC6265**
- ▶ Just ASCII plain text
 - ▶ Sent by server
 - ▶ **Stored in client** (database, filesystem, ...)
 - ▶ Returned by client when visiting page again
- ▶ Cookies can be set by the server for a particular path/domain
 - ▶ then sent for any page matching
- ▶ Multiple cookies may be set and returned
- ▶ Cookies may have a **limited lifetime**
 - ▶ set by Expires or Max-Age

Setting cookies

Server -> User Agent

```
Set-Cookie: SID=31d4d96e407aad42; Path=/; Secure; HttpOnly  
Set-Cookie: mylanguage=en-GB; Path=/; Domain=example.com
```

User Agent -> Server

```
Cookie: SID=31d4d96e407aad42; mylanguage=en-GB
```

Secure cookies?

RFC6265: *The Secure attribute limits the scope of the cookie to “secure” channels (**where “secure” is defined by the user agent**). When a cookie has the Secure attribute, the user agent will include the cookie in an HTTP request only if the request is transmitted over a secure channel (typically HTTP over Transport Layer Security (TLS) [RFC2818]).*

- ▶ ... provided browser obeys this
- ▶ still, no harm in using (defence in depth)

the HttpOnly attribute is similar, and forbids the browser from allowing JavaScript access to the cookie, in principle.

Expiry dates

Server -> User Agent

```
Set-Cookie: mylanguage=en-US; Expires=Wed, 09 Jun 2024 10:18:14 GMT
```

User Agent -> Server

```
Cookie: SID=31d4d96e407aad42; mylanguage=en-US
```

- ▶ Of course, no guarantee cookie is kept for 6 years...

Removing cookies

RFC6265: *To remove a cookie, the server returns a Set-Cookie header with an expiration date in the past. The server will be successful in removing the cookie only if the Path and the Domain attribute in the Set-Cookie header match the values used when the cookie was created.*

Server -> User Agent

```
Set-Cookie: lang=; Expires=Sun, 06 Nov 1994 08:49:37 GMT
```

User Agent -> Server

```
Cookie: SID=31d4d96e407aad42
```

- ▶ Again, no guarantee of what browser actually does
- ▶ ... if indeed the same browser is being used

Session hijacking

Web apps use session IDs as a credential

- ▶ if an attacker steals a SID, she is logged in!

This is **session hijacking**.

Many possible theft mechanisms:

- ▶ XSS, sniffing, interception
- ▶ or: calculate, guess, brute-force
- ▶ also **session fixation**
 - ▶ using same SID from unauthenticated to logged in
 - ▶ attacker grabs/sets SID before user visits site

Session hijacking defences

Web apps (or frameworks) should implement defences, and discard SIDs if something suspicious happens.

- ▶ Link SID to IP address of client
 - ▶ but problems if behind NAT, transparent proxies
 - ▶ ISP proxy pools mean need to use subnet, not IP
 - ▶ subnet may be shared with attacker!
- ▶ Link SID to HTTP Headers, e.g. User-Agent
 - ▶ but can be trivially faked. . . and usually guessed
 - ▶ . . . or captured (trick victim to visit recording site)

OWASP: Is the application vulnerable?

Poor Session ID (SIDs) management by:

- ▶ exposing SIDs in the URL (e.g., URL rewriting).
- ▶ SIDs are vulnerable to session fixation attacks.
- ▶ SIDs don't timeout, or sessions/tokens aren't invalidated in logout.
- ▶ SIDs are weak (small entropy, or predictable)
- ▶ Session IDs aren't rotated after a new login.

OWASP: How do I do things correctly?

See the

- ▶ [OWASP Session Management Cheat Sheet](#)

Or use a framework in which there is a strong degree of confidence that things have been done properly.

General Secure Programming advice: reuse believed-to-be-secure solutions as far as possible. It may be tempting to use the latest WhoJamig WebApp Framework but think twice unless you're sure it is well programmed for security, not just appearance

Outline

Introduction

Basics: HTTP

Authentication

Cookies and sessions

Summary

Review questions

HTTP Headers

- ▶ Describe three possible vulnerabilities for a web application posed by an attacker who fabricates HTTP headers rather than using the web app running via a reliable browser.
- ▶ Explain the reasons for using POST rather than GET. What security guarantees does it provide?

Cookies

- ▶ Consider an online grocery merchant that uses a cookie to store the user's shopping basket, including the list of product IDs and their prices, encrypted using a secret key derived from the SID. What threats might be posed and by whom?

References

Some examples were adapted from:

- ▶ *Innocent Code: a security wake-up call for web programmers* by Sverre H. Huseby, Wiley, 2004.

as well as the named RFCs and the OWASP resources.
